Foreshadowing postmodernist theory, Henry Kariel (1969) argued that political participation sometimes involves the creation of new forms of political reality, an idea precluded by Dahl's empirical studies of individual action in the policy process. Others criticized Dahl for finding interest group domination of politics, leaving little role for policy initiatives organized by government, but this criticism confused Dahl's pluralism with group theory. In addition, Dahl and pluralist theorists were frequently criticized as expressing a favorable view of the political status quo, although in writings after 1970 Dahl clearly indicated he had no such intention. In the final analysis, Dahl's pluralist theory of political power made a major and lasting contribution to the study of power, in that many in succeeding generations of political scientists used most of Dahl's basic methods in the study of power, although they often interpreted research results differently, as exemplified by Lowi's theory of "interest-group liberalism"—the unaccountable "islands of power." After 1980 much political science work in the study of power in public policymaking, in urban politics, and in interest group activity can be described as neopluralist, as much of Dahl's outlook has been retained but methodological and interpretive corrections have been made for the problems found in Dahl's pluralism (for instance, allowing for concern for the political agenda and recognition that islands of power exist). These neopluralist researchers include John W. Kingdon (1984), Jack L. Walker Jr. (1991), Frank R. Baumgartner and Bryan D. Jones (1993), Jeffrey M. Berry (1999), and Virginia Gray and David Lowery (2004).

In his studies of democracy, after 1970 Dahl turned from the pluralist theory approach to other approaches based upon comparative political studies and his own egalitarian philosophy. Dahl sometimes used the term polyarchy, rule by the many, rather than the controversial democracy. At first he stressed the usefulness of comparative indicators of democracy, emphasizing stable electoral competition among political elites (Polyarchy, 1971). Realizing that democracy is based on more than regular competitive elections, Dahl broadened his approach to include diversity of political communications, economic development level of society, tolerance of political oppositions, and institutional legitimacy as an antidote to military coups. In addition, Dahl explored issues concerning the extent of political participation and the control of the political agenda, advances beyond his initial pluralist theory. Moreover, Dahl exhibited an egalitarian impulse by exploring contradictions between unequal distribution of wealth and democracy, and he examined possibilities for wider participation in business decision making as a means for controlling corporate power. Dahl's comparative indices of democracy contributed to the theory of democratic peace, the finding that democracies almost never in the last century engaged in war with one another. Comparative indices of democracy are now widely used as a basis for the evaluation of political regimes by political and economic-development decision makers. The conclusions of Dahl's thirty years of writing in the comparative and philosophical vein are summarized in nontechnical language in his On Democracy (1998).

Dahl is also known for exploring the links between the logical bases of U.S. governmental and political institutions and political outcomes. At first, in Preface to Democratic Theory (1956), Dahl argued that the logic of majority voting did not pose a critical threat to civil liberties and democracy, but later, in How Democratic Is the American Constitution? (2003), he became concerned about the effects of equal state representation in the Senate and of imbalanced campaign contributions on representative democracy.

DALITS

Historically, Hindu society in India has been characterized by a high degree of social stratification and institutional inequality governed by the caste system. The caste system as a societal order of social, economic, and religious governance for Hindus is based on the principle of inequality and unequal rights. The dalits or the untouchables (known as scheduled castes in government parlance) stand at the bottom of the caste hierarchy, and were historically denied equal rights to property, education, and business, as well as civil, cultural, and religious rights. They were also considered to be polluting, and they suffered from social and physical segregation and isolation. The result was a high level of deprivation and poverty.

SOCIAL MOVEMENTS

Past religious and cultural movements, such as Buddhism, opposed Brahmanic Hinduism and attempted to construct Indian society on principles of equality and fraternity. The dalits themselves initiated social movements against the denial of equal rights and oppression in the latter half of the nineteenth century and the first half of the twentieth century, notably the social-political movement of the Indian reformer and politician Bhimrao Ramji Ambedkar (1891–1956). During the 1970s and the 1980s, collective action emerged among the dalits in the form of the Dalit Panther movement in Maharashtra State and the Dalit Sangarsh Samiti in Karnataka, and the rise of such political parties as the Bahujan Samaj Party in the north, and similar efforts throughout the country. A strong nongovernmental organization movement also emerged, particularly in south India. In 1998 these groups formed a coalition of civil society organizations and activists: the National Campaign on Dalit Human Rights. This coalition facilitated the establishment of an International Dalit Solidarity Network in Europe and the United States.

By 2006, dalit assertion has transcended national boundaries with the dalit diaspora organizing itself into the Ambedkar Mission Society, the Federation of Ambedkarite and Buddhist Organization, the Voice of Dalit International in the United Kingdom, Volunteers in Service to India’s Oppressed and Neglected in the United States, and similar organizations in Canada. These organizations generate and disseminate literature about problems of the dalits, undertake advocacy, and use modern information and communication tools to generate discussion and build solidarity.

CONSTITUTIONAL PROVISIONS AND STRATEGIES OF SCHEDULE CASTE EMPOWERMENT

The constitution of India (1950) guarantees equality before the law (Article 14); prohibits discrimination on the basis of religion, race, caste, sex, or place of birth (Article 15); and abolished untouchability (Article 17). It further assigned responsibility to the state for the promotion of the educational and economic interests of the dalits (Article 46). On this basis, legal safeguards have been provided, including the Anti-Untouchability Act of 1955, and affirmative action policies in public employment, educational institutions, and the legislature, and other measures for the general economic empowerment of the dalit community. Government policies thus aim to overcome the multiple deprivations that dalits have inherited from exclusion in the past, and provide protection against exclusion and discrimination in the present.

Affirmative action policies are confined to the public sector. In the absence of such policies for the private sector, the state has developed programs for the economic, educational, and social empowerment of the dalits with a focus on improving the private ownership of fixed capital assets, human resource capabilities, and access to basic civil amenities, among other things.

CHANGE AND THE STATUS OF DALITS IN THE TWENTY-FIRST CENTURY

Government policies from 1950 to 2000 indicate both positive change and continuity in deprivation. There has indeed been some improvement. In 2000 about 17 percent of dalits cultivated land, and about 12 percent of dalits in rural areas and 28 percent in urban areas owned small businesses. Literacy rates among dalits have risen from 10.27 percent in 1960 to 54.69 percent in 2001.
The unemployment rate in rural areas has been reduced from 6.77 percent in 1978 to 5 percent in 2000, and from 7.37 percent to 5.20 percent in urban areas for the same periods. Lingering limitations in access to assets are the residue of a similar denial in the past.

Affirmative action policies have seen limited, yet positive, gains. The number of dalits employed in central government jobs increased in 2002, along with the number of dalit employees in public sector undertakings. The number of dalits employed in government banks also rose in 2004. In education, about a third of dalit students enrolled in universities and colleges were pursuing higher education in desirable programs because of reservation policies. As a consequence of such positive changes, poverty among dalits declined from 58 percent in 1984 to 37 percent in 2000 in rural areas, and from 56 percent in 1983 to 38 percent in 2000 in urban areas. Furthermore, caste discrimination against dalits in civil, cultural, and religious spheres has been reduced in some public spheres, although more so in urban than in rural areas.

Notwithstanding these gains, India’s dalits continue to suffer in terms of absolute levels of deprivation and indicators of human development. About 70 percent of dalits inhabit rural areas; in 2000 about two-thirds of dalit rural households were landless or near landless (the figure is one-third for nondalits). Less than one-third of the dalit population had access to capital assets (40% for nondalits); 60 percent of dalits were dependent upon wage labor (25% for nondalits); and the dalit unemployment and literacy rate was 5.5 percent and 54.69 percent respectively, compared to 3 percent and 58 percent for nondalits. In addition, the prevalence of anemia among dalit women and mortality among children was high.

Various studies indicate that dalits continue to face discrimination in market and nonmarket transactions, in social services (education, health, and housing), and in political participation. Thus, there remains a long way to go before India’s dalits can imagine a reasonable degree of dignity in their lives and livelihoods.

POLICY INITIATIVES

In 1992 the Indian government withdrew from some public spheres under an overall policy of liberalization. This development weakened the possibility of public sector employment for dalits. The government has made efforts to establish affirmative action policies that apply to the private sector; these efforts have seen response from India’s corporate sector in 2006, but they have not yet taken any shape in terms of policy. However, other initiatives include reserved spots for dalits in private educational institutions, as well as scholarships for research and technical education. In addition, in 2005 India passed the Employment Guarantee Act, which ensures minimum

employment for rural laborers. Such initiatives are likely to enhance the status of the dalits.

During 2006, the Indian government has taken new initiative by extending reservation to Other Backward Castes in public educational institutions and proposed to extend the same to private educational institutions. The reservation in private education institutions would also benefit the Schedule Castes. The progressive extensions of reservation to Other Backward Castes has widened and strengthened the safeguards against the hierarchical discrimination faced by different sections of lower castes. This has encouraged solidarity among Scheduled Castes and Other Backward Castes.

**DANCE**

Dance, or the human body making rhythmic patterns in time and space for a purpose transcending utility, has been approached by anthropologists as one aspect of human behavior inextricably bound up with all those aspects that constitute what we call culture. Early ethnographers attended to dance as an adjunct to ritual or as an accompaniment to leisure social activities. Contemporary scholars examine it as belonging to the more general category of embodied knowledge. Their scope extends to classical performance traditions, modern popular forms, and communally embedded traditional dance.

Throughout human history, dance has always elicited powerful responses—on one hand, it has been banned, feared, seen as a corrupting influence, criticized for its sexual nature, and anathema to those who privilege the mind; on the other, dance has been praised for its ability to entertain, viewed as the essential element in rituals of healing, transformation from one state to another, and thanksgiving, and as ordered movement, a symbol of a cosmic “great chain of being.” Through its performance by the human body and its ability to elicit a kinesthetic response in performer and viewer alike, it becomes elemental. Its universality across cultures is equated by the strength of human responses to it, in which there appears to be no neutral position. Anthropologist Maurice Bloch, in his influential 1974 article, argues for the language of song, dance, and music as a special form of assertion toward which no argument is possible. Whatever meanings are encoded in these forms, the listener or viewer may only agree or disagree. There is no dialogue possible.

The medium of dance, composed by individuals and embodied by other individuals, creates meanings that are polysemous and multivoical. The choreographer of a piece or a ritual may have one message to convey, the performers other interpretations, and the audience yet other understandings. This quality compounds the difficulties faced by scholars who wish to understand how and why dance occupies the position it does in society. Dance can be viewed for its formal aspects, its meanings or content, or for the relationships it has to its larger social context. In the history of American anthropology, the last approach has been the most popular. The reasons for this have to do with an implicit hierarchy of ethnographic areas of inquiry with the arts being relegated to the least central to understanding society. Even within the arts, visual arts have always been favored, perhaps because they are easier to document, unlike performing arts, whose “products” are ephemeral. Secondly, dance is notoriously hard to observe, record, and analyze. A focus on who participates in dance and how it functions within society made dance seem like other social categories. Early descriptions paid minimal attention to form, preferring the safer ground of functional analysis.

Ironically, French anthropologist Marcel Mauss (1872–1950) had no such hesitation in exploring the body in motion. In his article “Body Techniques” (1934), he examined body actions in ordinary life, relating them to expectations about gender, about practice, and about habits of the body. His definition of techniques of the body—highly developed body actions that embody aspects of a given culture—was the foundation for Pierre Bourdieu’s (1930–2002) *habitus*, a notion that has influenced much of contemporary social science.

American anthropologist Franz Boas (1858–1942) acknowledged dance as a universal human phenomenon and, in the case of the Kwakiutl of the northwest coast of North America, as an essential part of their culture, but he found the form of dance more difficult to describe than visual arts, house types, music, or kinship systems. He was one of the first, however, to use film to record dance. Although the first system for notating was published in 1588 (*Orchesographie* by Thoinot Arbeau), it would not be until the 1930s, when Hungarian dancer Rudolf von Laban (1879–1958) created a dance and movement notation based on universal and arbitrary symbols, that it was possible to make an adequate record of dance that might be a basis for formal analysis. Laban’s system, *labanotation*, and its offshoot, *effort-shape notation*, revolutionized the way in which dance is described and preserved. While most dance ethnographers prefer their own shorthand systems, supplemented by film, for field research, these two notation systems prove invaluable for both structural analyses of dance as well as for permanent records. European folklorists and ethnomusicologists were much quicker than their American counterparts to document such formal aspects of dance as steps, choreography, movement patterns, and floor plans. They were also quicker to use *labanotation* and *effort-shape* in their work (Royce 1977).

Attention to the formal aspects of dance did not occur in the United States until dancers trained as anthropologists entered the field. Katherine Dunham (1909–2006), who worked in Haiti and the Caribbean, and Pearl Primus (1919–1994), who examined West African dance and its American forms, approached their subject as dancers and as anthropologists. As dancers, they were comfortable with the dance itself, settling it in their own bodies. As anthropologists, they documented its purpose in those societies they studied. Both women ultimately focused on theatrical performance as a way of bringing the richness of African diasporic cultures to the widest possible audience. Regarded as performers rather than as scholars, their important work was largely ignored.
Gertrude P. Kurath (1903–1992), a dancer with degrees in music, drama, and art history, was initially more successful. Invited by anthropologist Sol Tax (1907–1995) to write an article on dance ethnology for the first issue of *Current Anthropology*, Kurath defined and laid out the shape of research on dance within American anthropology. Sound research on dance, she wrote, could only be done by “dancers who have achieved the insight and point of view of the ethnologist, or by musicians and ethnologists with dance training” (Kurath 1960, p. 247). This, indeed, has been the pattern, with dance-trained anthropologists forming the majority of dance scholars. Kurath herself documented dance in cultures as widely separated as the American Southwest, Mexico, eastern and southern Europe, and ancient Mesoamerica, as well as Iroquois dance. Her most-long-lasting contributions to the anthropology of dance have been her meticulous ethnographic description, and her development and use of a notation system easily learned and easily understood by readers. Kurath’s superb monograph, *Music and Dance of the Tewa Pueblos* (written with Antonio Garcia, 1970) provided ethnographer Jill Sweet a foundation on which to trace the trajectory of Tewa dance. Sweet, with forty years of involvement with the Tewa, published a second edition of her book *Dances of the Tewa Pueblo Indians* in 2004. Most significantly, she included the voices of Tewa themselves, who reflect on the continuities and disjunctions of their dance.

In the late 1960s and 1970s, a small group of anthropologists elaborated different approaches to dance within anthropology. Adrienne Kaeppler used linguistic analysis to explore the structure of Tongan dance. Drid Williams argued for a linguistic approach based on transformational grammar. Judith Lynne Hanna, working initially with West African and African diasporic dance, employed communications theory as a way to examine dance. Joann Kealinohomoku took the work of Boas and Melville Herskovits (1895–1963) in new directions, looking at dance holistically as performed by the biological, language-using, social, culturally embedded human being. Anya Peterson Royce weighed the merits of historic, comparative, symbolic, and structural approaches to dance as an aspect of human society. The early contributions of these scholars to the emergence of the anthropology of dance as a scientific field of inquiry is the subject of a 2005 volume, *Anthropologie de la Danse (Anthropology of Dance)*. Its editors, Andrée Grau and Georgiana Wierre-Gore, included important European scholars whose work is both fundamental and provocative. These include Rodryk Lange, John Blacking, György Martin, Ernő Pesovár, Anca Giurchescu, and Egil Bakka.

Since the 1980s, dance scholars have kept pace with the discourse of anthropology as it has dealt with issues such as borders and boundaries, postcolonial societies, exile and appropriation, gender, power and agency, the articulation of us and them, and not least, an embodied anthropology of the senses. The tango and the samba provided a multivocalic point of entry into matters of exile, identity, agency, and embodied memory and action for three anthropologists and their work: Barbara Browning’s *Samba: Resistance in Motion* (1995), Marta Savigliano’s *Tango and the Political Economy of Passion* (1995), and Julie Taylor’s *Paper Tangu* (1998). All three authors capture what it means to be embodied in the dance, and communicate it in their writing. Browning writes of the way in which the dancing body communicates as a complex speaking of the body. Savigliano, an Argentine herself, describes the tango from the inside out in words that allow the reader not only to “see” the dance but also to “feel” it. Taylor, who lived in Argentina for more than twenty years, takes us beyond the observable steps into the meanings deep in the dancers’ bodies, and does so in language that situates the reader in the tango itself. Taylor and Savigliano speak eloquently and powerfully to the issues of exile and appropriation, the recombination of old stereotypes with new territories, and introspection and memory in the face of political terror. These key themes in contemporary anthropology gain new significance from their embodied treatment.

Browning’s important contribution is to speak of the agency in the body, especially the danced body. She writes, “the insistence of Brazilians to keep dancing is not a means of forgetting but rather a perseverance, an unrelenting attempt to intellectualize, theorize, understand a history and a present of social injustice” (Browning 1995, p. 167). The active, creative, and creating body in dance is the subject of studies by Susan Leigh Foster in her perceptive commentaries on theory, by Cynthia Novack (1947–1996), who examined contact improvisation and American culture, and by Kazuko Yamazaki, who describes changing Japanese notions about the gendered body and its implications for innovation in dance.

The nuanced complexities of cultural perceptions and the social manipulations of dance and embodied movement have been the focus of several recent studies. Two of those are Jennifer Nevile’s *The Eloquent Body: Dance and Humanist Culture in Fifteenth-Century Italy* (2004) and Anne Décoret-Ahiha’s *Les Danses Exotiques en France, 1880–1940* (2004). Nevile discusses the moral divide between the noble dances of the Italian court and the graceless dances of the peasants. Dancing masters, and the court humanists who were the arbiters of intellectual and moral engagement, molded their pupils’ bodies into the ordered, virtuous symbols of nobility. The peasantry, in contrast, were divorced from any philosophical foundations of morality, their dances therefore reflecting that lack in their sensual formlessness (Nevile 2004, pp. 2–3).
Décoret-Ahiha contrasts nineteenth-century French popular dance with popular dance between 1900 and 1940. Both periods were fascinated with the "exotic," but how exotic was defined differed. Nineteenth-century exoticism in the form of world's fairs and ethnological exhibits found a welcome audience of people who flocked to see these "primitive" and strange peoples and customs. At the beginning of the twentieth century, exotic dance dominated the music hall scene and drawing rooms. This shifted as artists and companies from all over the world made their way to Paris. Sergei Diaghilev's (1872–1929) Ballets Russes, with its lush ballets on Oriental themes and works that evoked the Russian soul, was one such company. The author's interest lies in the discourses produced by these periods of fascination with the exotic and their impact on society and on the dance itself. Hers is a richly textured commentary that enriches our notion of the "exotic other."

Anthropology of dance has expanded its scope to include studies of form as well as meaning, Western and non-Western dance, historic and contemporary phenomena, classical forms as well as popular or traditional dance, comparative and cross-genre performance traditions, and such issues as aesthetics, virtuosity, and the relationship between creator, performer, and audience. These topics have allowed scholars to move beyond ethnographic description and surface meaning to the kind of theory-building that contributes to all those fields concerned with human thought and behavior. It builds, interestingly enough, upon the generalizations, comparisons, and theories about style and structure that Boas and Claude Lévi-Strauss developed in the visual arts and oral genres. The shifts within anthropology toward process rather than structure, and performance rather than competence, have led scholars to an acknowledgment of the body, embodiment, and embodied knowledge as essential ways of being and of knowing (Royce 2004).

The field has not only grown since Kurath's 1960 statement of its potential. One has only to compare Kaeppler's 1978 review of the field with Susan Reed's 1998 review. Since 1998, dance scholarship has expanded further. Most importantly, the field has established itself within anthropology as a focus and method that contributes to general theories of culture and society. Whatever issues anthropologists define as worthy of examination, they must pay attention to their embodiment in the repertoire of individual actors and societies. Anthropologists will not be successful in that endeavor unless they acknowledge and practice embodied ways of knowing. They have recognized that dance and performance provide unique and subtle entryways to artistic expression. They have now begun to see the value of that lens for examining cultural understanding as a whole.

DARFUR

Darfur is the westernmost province of Sudan. A remote region whose concerns were long eclipsed by the civil war in South Sudan, Darfur became a center of international concern when a new civil war emerged there in 2003. The war was fought between nominally “black” ethnic groups and Arab militias called janjaweed who, with support from the Sudanese government, killed and displaced hundreds of thousands of people. The violence had roots in economic underdevelopment and long-standing conflicts over land, but became far more destructive as external political influences grew and as conceptions of ethnic identity changed.

EVOLUTION OF THE CONFLICT

The name Darfur is Arabic, meaning “home of the Fur,” one of the territory’s largest tribes, but the province is home to at least three dozen distinct ethnic groups and many more subgroups. Today, nearly the entire population of Darfur is Muslim, owing to a policy of Islamization carried out in the fourteenth and fifteenth centuries when Darfur was an independent sultanate.

The terms Arab and black (or, alternatively, African) are broad categories used to identify the general affiliation of smaller tribes. The terms do not necessarily relate to physical appearance, and they have not always been decisive in determining political alignments. Arab groups are generally herdsmen, whereas most (but not all) of the black tribes are sedentary farmers. These differing types of agriculture can produce disputes over land use, which in some cases leads to violence between tribes. Until the end of the twentieth century, such conflicts in Darfur were generally contained and limited; although intergroup conflict has long been a feature of Darfur’s history, it existed alongside considerable constructive economic and social relationships. Intermarriage was common between Arab and African tribes. Cattle herdsmen and sedentary farmers traded for agricultural products such as grains and milk, as well as for grazing rights from farmers. Prosperous sedentary farmers sometimes invested in cattle, further blurring the distinctions between the groups.

Darfur contains rich agricultural land, but the entire region has been threatened by desertification since the 1970s. It experienced a famine in 1984. Dwindling fertile land combined with the lack of alternative economic development increased the potential for conflict at a time when forces from outside began to intervene. Also in the 1970s the Sudanese government began to dismantle the Native Administration system that had been set up by British colonial authorities, by which tribal chiefs were granted considerable autonomy and were often able to mediate intergroup conflict. In the late 1970s and early 1980s Chad’s civil war increased the flow of arms in the region, and increased the interests of both Chadian and Libyan governments in the politics of Darfur. In the mid-1980s the Sudanese government began arming militias of Arab tribes in Darfur, fearing that the civil war in the south might spread. These external influences encouraged groups in Darfur to identify themselves as Arab or black and to make this the defining distinction in determining their political affiliation. Along with the influx of weapons from outside, this shift in ethnic identity helped to broaden conflicts that might otherwise have remained isolated.

From 1987 to 1989 a dispute over grazing land erupted between the Fur and some cattle-herding tribes in northern Darfur. The conflict quickly escalated. A new organization called the Arab Gathering emerged, organizing twenty-seven smaller tribes and asserting a platform of Arab supremacy. The Fur conflict also marked the first prominent appearance of Janjaweed fighters, bands of armed men riding horses and camels who attacked Fur villages. By its end, the Fur-Arab conflict killed around 3,000 people and destroyed hundreds of villages.

In the mid-1990s the Sudanese government split Darfur into separate administrative regions, a policy that effectively transferred control of much land to Arab-oriented tribes. In 1996 violence erupted again, this time between Arab militias and the non-Arab Masalit tribe. Masalit villages were burned by Janjaweed attacks, and more than 100,000 Masalit fled into Chad and other neighboring countries.

In the late 1990s Masalit exiles based in Egypt began publishing some of the first international warnings about accelerating ethnic cleansing in Darfur, alleging that attacks on the Masalit and other black groups were planned by Sudanese military leaders. These allegations were initially disregarded by western governments and major human rights organizations, who cast the Darfur conflict as local tribal violence or did not report on events there at all. The United Nations refugee agency refused protection to many asylum seekers from Darfur, arguing that either they were not credible or were not sufficiently at risk.

2003: DARFUR ERUPTS

After 2000 two major opposition organizations emerged among the black population. The first was the Justice and Equality Movement (JEM), which had an Islamist ideological orientation and maintained links with religious leaders who had split from the Sudanese government in the 1990s. Another group, the Sudanese Liberation Movement/Army (SLA) modeled itself on the southern Sudanese Peoples Liberation Movement/Army (SPLA), and offered a secular platform. In February 2003 the JEM
and SLA launched successful military assaults on government targets in Darfur.

With the outbreak of full-fledged civil war, the government adopted what the International Crisis Group called a "scorched-earth" strategy to defeat the rebels. This relied heavily on the Janjaweed to attack the civilian populations that might support the rebellion, backed up by government air strikes. The Janjaweed attacks included mass killings, rapes, whippings, cattle theft, and the burning of hundreds of villages. A small force of 7,000 African Union soldiers entered Darfur in August 2004, but failed to stop the violence. Survivors fled, especially to Chad, and by late 2005 fighting began to cross the border. By the beginning of 2006 up to 2 million people were displaced from their homes and at least 180,000 were dead, most of them members of non-Arab/black tribes.

After 2003 debate grew about whether the Sudanese government and the Arab militias were guilty of genocide, a label that would increase the pressure for strong international intervention. But the complex origins of the violence and the fact that the worst abuses were committed by diffuse Janjaweed bands rather than by government troops fed the dispute about how the atrocities should be described.

On July 23, 2004, the U.S. Congress passed a resolution calling the Darfur conflict a genocide, a position later adopted by the Bush administration. On January 25, 2005 a UN Commission of Inquiry confirmed that "government forces and militias" may be guilty of crimes against humanity in waging a violent campaign to defeat the rebellion. But the commission concluded that the violence could not be labeled genocide because the government's intent was not to destroy any particular ethnic or racial group, the essential legal criteria for applying the genocide label.

On March 29, 2005, the UN Security Council asked the International Criminal Court to investigate the Darfur atrocities. In May 2006 the government of Sudan signed a peace accord with the SLA, but the JEM rejected the agreement, as did splinter factions of the SLA. The UN reported that violence in Darfur actually increased in the months after the accord; divisions among the rebels coupled with the difficulty in disarming Janjaweed militias posed major challenges to restoring order.

DARWIN, CHARLES
1809–1882

Charles Robert Darwin is regarded as one of the greatest scientists who ever lived. He was the son of a wealthy provincial British doctor and entered into the study of medicine at Edinburgh University, but did not like it. He was then expected by his family to become a clergyman and graduated from Cambridge University. However, he was unenthused about pursuing a career in the church.

Fortunately for him, as well as the world of the biological sciences, he was offered an unpaid position assisting the captain of the British survey ship Beagle. From this little ship, Darwin spent the next five years exploring the natural world. His observations fostered a deep interest in biology and geology and motivated him to pursue the sciences as a career and eventually develop the theory of natural selection.

Charles Darwin’s theory of evolution by natural selection is the only scientific explanation for the nature and variety of life on our planet. Moreover, if life in other parts of our galaxy is governed by the same natural laws that govern it here, then Darwin’s logic also explains the varieties of life in distant parts of our galaxy. However, it does not explain the origin of life itself. Darwin’s theory leaves the very beginning of life—the formation of the first primitive organic molecules—to chemists, physicists, and maybe even theologians. This entry focuses on the logic of how natural selection shapes the tools that enable organ-
isms to survive the challenges of their environment, on
some misconceptions about the theory of evolution, and
on how evolutionary theory can help us understand human behavior. Finally, it briefly mentions some of the scientific and political controversies associated with current evolutionary thinking. Those interested in the vast evidence for Darwin’s theory should consult Mark Pagel’s Encyclopedia of Evolution (2002).

DARWIN’S FINCHES AND THE LOGIC OF NATURAL SELECTION
The Galapagos Archipelago is a group of islands off the coast of Peru. Eons ago, a single species of finch landed on one of the islands. Because resources for survival and reproduction were limited, the finches began competing for them. Some finches migrated to other islands. Since the environments of the islands differed, various biological tools, such as the shape of the birds’ beaks, differed in their effectiveness for dealing with these environments. Over time, fourteen species of finches evolved in the archipelago. Although the species vary in many ways, such as in size and coloration, differences in their beaks are particularly salient. The study of how the beaks of Galapagos finches contribute to survival and reproduction in the environments of the different islands has contributed greatly to the development of evolutionary theory (Weiner 1994).

Biological tools that contribute to an individual’s survival and reproduction are called adaptations. An adaptation is a trait—an anatomical structure, physiological process, or behavior pattern—that contributes more to an individual’s ability to survive, grow, or reproduce in comparison with alternate traits in the population. The large, powerful beak of the Geospiza magnirostris finch, useful for cracking large seeds, and the small, delicate beak of Certhidea olivacea, useful for extracting insects from the bark of trees, provide examples. Natural selection is the differential contribution of offspring to the next generation by genetically different members of a population, that is, the number of progeny of finches with genes for different beaks. The logic of natural selection can be explained in terms of assumptions and inferences that follow from the assumptions (Crawford 1998).

Assumption 1: The number of descendents of organisms in a population can grow exponentially.
Assumption 2: Resources enabling individuals in a population to exist can expand only arithmetically.
Assumption 3: Some of the variation in these traits is genetic in origin.
Assumption 4: Individuals differ on traits that enable them to survive and reproduce.
Assumption 5: Some of the variation in these traits is genetically different members of a population (natural selection, by definition).

Inference A: Competition for survival and reproduction ensues between individuals in a population.

Inference B: There is “differential contribution of offspring to the next generation by genetically different members of a population” (natural selection, by definition).

Inference C: Over many generations, “anatomical structures, physiological processes or behavior patterns that contribute more to individuals’ ability to survive, grow and reproduce in comparison with alternate traits in the population” (adaptations, by definition) are created.

In summary, some feature of the environment—for example, the arrival of a new predator or a change in climate—poses a problem for organisms in a population. A solution (e.g., longer legs, thicker fur) aids survival and reproduction. The above assumptions and inferences explain how natural selection provides the solution. Preexisting adaptations, sometimes called preadaptations, provide both stepping stones and limits to the solutions natural selection can provide (Pagel 2002).

SOME MISCONCEPTIONS ABOUT DARWIN’S THEORY
Assumptions 1, 2, and 3 do not require nature to be “red in tooth and claw,” as the poet Alfred Tennyson described it in In Memoriam (1850). A variety of subtle, and not so subtle, adaptations help individuals survive and reproduce. For example, animals in herds, such as wildebeests, may minimize the relative risk of predation by maneuvering to place other animals between themselves and predators (Hamilton 1971). Many types of camouflage coloration have evolved to protect organisms from their predators (Pagel 2002).

Although genes are involved in the development of all adaptations, assumptions 4 and 5 do not require that differences between individuals in evolved traits are genetically preprogrammed. Traits whose development is influenced by environmental factors are called facultative traits. Although male white-crowned sparrows, for example, cannot learn the song of another species, when they are nestlings they must hear an adult male of their own species sing and then themselves sing as juveniles if they are to sing a full song as adults (Konishi 1965).
Organisms do not evolve to act for the good of their species or the groups with which they live (Williams 1966). Since an organism’s time and energy are limited, an organism that helped a member of its species or group would pay a reproductive cost (i.e., have fewer offspring) to do the helping. Hence, one of its competitors who did not help would leave more offspring, and its kind would spread through the group or species at the expense of the helpers. However, modern Darwinists have two methods of explaining the widespread helping behavior seen in nature. The first is the evolution of cooperation, in which both parties increase their reproductive success by helping the other (Trivers 1971). The second is through helping genetic kin (Hamilton 1964). Genetic kin, such as brothers and sisters, have copies of genes that are identical to those of common ancestors. If a brother inherited a gene from his mother that predisposes him to help his sister produce offspring, that helping gene can spread through the sister’s offspring (his nieces and nephews) even though it reduces the brother’s own reproductive success. The reason is that the sister has a fifty-fifty chance of inheriting the same helping gene from their mother and passing it on to her children, her brother’s nieces and nephews.

Finally, natural selection does not have a goal. It is a purely mechanical process: traits that contribute more to survival and reproduction spread at the expense of traits that contribute less to survival and reproduction. Humans may evolve to be godlike creatures in the distant future. However, if this happens it will not be because natural selection had the goal of producing such beings.

**EVOLUTIONARY PSYCHOLOGY**

Evolutionary psychology uses the principles of natural selection to understand the origin and functioning of the cognitive and emotional adaptations that helped us deal with problems in our ancestral environment, known as the environment of evolutionary adaptedness, and how those mechanisms function now (Crawford and Anderson 1989).

Mating of close genetic relatives, for example, can be detrimental to reproduction and survival because it brings together deleterious recessive alleles, such as those causing some genetic diseases, in the offspring of such mates. Some Darwinists have argued that intimate rearing of brothers and sisters during their first few years, which reduces or eliminates adult sexual attraction between them, may reflect one mechanism humans evolved to avoid this problem (Westermarck 1891). This argument is supported by evidence from: (1) boys and girls reared in the same children’s houses in Israeli kibbutzim, who rarely find each other sexually attractive as adults (Sheper 1983); (2) the reduced success of Chinese shim pau marriages, in which a genetically unrelated baby girl is adopted into a family at birth with the expectation that she will marry a son of the family at their sexual maturity (Wolf 1995); and (3) sexual attraction between adult genetic siblings who were separated at birth (Bevc and Silverman 2000).

In the upper panel of Figure 1, the assumption is that brothers and sisters with genes enabling them to develop psychological mechanisms to avoid incest had greater lifetime reproductive success across evolutionary time than those who did not. The result is the ancestral genotype for the avoidance mental mechanism. The ancestral developmental environment—intimate rearing with genetic siblings—produced the genetically organized ancestral cognitive and emotional mechanism(s) (the ancestral phenotype) that reduced sexual attraction between adult childhood intimates. The ancestral immediate environment refers to encounters between sexually mature, ancestral, opposite-sex individuals. Finally, natural selection favored the genes that enabled the development of the avoidance mental mechanisms.

The bottom panel represents an infinitesimal segment of evolutionary time—a few years in an Israeli kibbutz or a Chinese shim pau marriage or the meeting of an adult brother and sister who were reared apart from birth. In all cases, the putative adaptation functions as it evolved to function with respect to childhood intimates. However, because it functions in novel environments, its decision processes produce consequences that do not serve its evolutionary purpose. That is, it does nothing to prevent the mating of the genetic siblings, while reducing the likelihood of the success of the kibbutz and shim pau marriages.

Finally, evolutionary psychology is concerned with: (1) the problems that our hominid and primate ancestors encountered in their daily lives; (2) the psychological adaptations that natural selection shaped to help deal with those problems; and (3) the way the resulting evolved adaptations function in current environments (Crawford and Anderson, 1989).

**CONTROVERSIES ABOUT DARWINISM AND HUMAN BEHAVIOR**

Because of the great explanatory potential of Darwin’s theory of evolution, it engenders continuing scientific, religious, political, and social controversy. For example, if biologically based race, gender, and social class differences in anatomy, physiology, or behavior exist, then evolutionary theory helps explain their origin and significance (Degler 1991; Pagel 2002). However, the most salient issue—the one that underlies most controversies—is the degree of genetic specialization of evolved cognitive and emotional behavior–producing mechanisms. If natural selection produced primarily general-purpose psychologi-
cal mechanisms, as many social anthropologists and social activists argue, then evolutionary theory is of limited use in understanding human behavior. However, if it produced genetically highly-specialized psychological mechanisms, as most evolutionary psychologists argue (Barkow et al. 1992), then it is invaluable for understanding...
Table 1 shows the consequences for social policy of these two perspectives. The assumption underlying the table is that although specialized peripheral, information-processing mechanisms produce behavior, these specialized mechanisms can be assumed to develop from either a low or a high degree of innate genetic specialization of development. The columns under “Possible States of Nature” describe the possible states of the ancestral genotype shown in Figure 1. The rows indicate the two approaches to developing scientific explanations. Note that several different scientific approaches are listed in each row. The four cells in the table enumerate the outcomes of pairs of possibilities, that is, of pairing a high degree of genetic specialization with the scientific belief in a low degree of genetic specialization. Two cells describe valid outcomes. The two cells labeled “Evolutionary Psychologists’ Risks” and “Social Constructionists’ Risk” describe invalid outcomes. Many social activists, such as feminists and social constructionists, assume that the consequences of either making an evolutionary psychologist’s error or living in a society where ancestral evolved adaptations have an impact on current life, liberty, and happiness are so grave that they reject the possibility of the scientific explanations in the bottom row of the table.

Evolutionary psychologists reject this view. First, they worry about the suffering that could be caused by the

social constructionist errors shown in Table 1. Second, they claim that accurate scientific knowledge about the human mind is crucial for developing more caring and harmonious societies. Third, they claim that natural selection has given the human species many evolved cognitive and emotional mechanisms, such as those underlying reciprocity and kinship, which if their functioning is understood can help us produce a better world. Fourth, they claim that evolutionary psychology is in fact an environmentalist discipline (Crawford and Anderson 1989)—the specialized psychological mechanisms that produce behavior, described in Figure 1, evolved to help humans deal with problems and stresses in their environments. Hence, understanding how these evolved cognitive and emotional mechanisms work can help us create better places to pursue life, liberty, and happiness.

DARWINISM, SOCIAL

Social Darwinism is a philosophical, economic, social, and scientific movement that claims that the way society functions is, and ought to be, a reflection of the methods and movements of biological evolution. The term is generally applied to thinkers from around 1850 to the end of the nineteenth century, although the term itself was not popularized until the publication of Richard Hofstadter’s Social Darwinism in American Thought in 1944. Despite the title’s reference to Charles Darwin (1809–1882), most scholars think that his fellow English evolutionist Herbert Spencer (1820–1903) was a far more influential figure in Britain and America.

Postulated links between society and biology are as old as evolutionary thinking. In the early eighteenth century, evolutionists such as Denis Diderot (1713–1784) saw biological evolution—the natural rise of organisms from primitive beginnings to sophisticated life-forms, including humans—reflected in the rise of societies. European evolutionists believed societies evolved in the same way organisms did, rising from the savages of Africa and other barbaric (i.e. non-European) parts of the world to the supremely civilized peoples of western Europe. At the end of the eighteenth century, later evolutionists, including Charles Darwin’s grandfather Erasmus, likewise saw society as a mirror of what happens in the world of organisms, and like everyone else they happily conflated the way things are with the way things ought to be. Progress was the backbone of evolutionary thinking—from the simple to the complex, from the less desirable to the more desirable, from the monad to the man (in the language of the day)—and the way that things had been taken as a guide to the way that things ought to be, then and in the future.

THE NINETEENTH CENTURY

In the middle of the nineteenth century, Herbert Spencer began his dizzying rise to fame and influence, casting a
spell over Victorian Britain and much of the rest of the world that lasted until Queen Victoria died in 1901. Spencer was explicit in his belief that the patterns of society were reflected in the ways of biological development; indeed for him they were all part of one world-encompassing process, a process that was perpetually pushing upward, until the human species emerged at the top. Spencer was a liberal in the old-fashioned sense of disliking state interference and (particularly in his early years) he endorsed a strong program of laissez-faire, believing that the government should stay out of everything: the economy, education, welfare, even the provision of light-houses to guide ships to harbor. This was, in Spencer’s view, the only way to guarantee progress.

Superficially Spencer’s worldview seemed like a logical application of Charles Darwin’s theory of evolution, presented in his *On the Origin of Species* in 1859. There Darwin argued that an ongoing, bloody struggle for existence leads to natural selection, the motive force behind organic change, what Darwin called “descent with modification.” Social Darwinism sees a direct corollary between struggle in the biological world and struggle in the social world, with winners moving upward to success and losers eliminated: losing organisms fail to reproduce, losing firms go bust, losing people starve.

In reality, things are a bit more complex. Darwin himself was reluctant to draw a parallel between biological and social evolution. He certainly did believe that certain peoples were superior to others: typically Victorian, he believed the English were superior to other Europeans, and Europeans were superior to everyone else; but he also approved strongly of moves to ameliorate the woes of the less successful. Spencer himself held views far more complex than his legend gives him credit for. In many respects, he saw struggle between peoples as stupid and not at all conducive to progress. He was strongly against militarism and presciently believed the end-of-the-century arms race between Britain and Germany, as each country built ever-bigger battle ships, to be absolute madness.

Spencer’s followers were equally complex, especially those in America. Some, like sociologist William Graham Sumner (1840–1910), seem at times to be outdoing the master in prescribing brutal socioeconomic systems, but most held more sophisticated views. The great Scottish-born industrialist Andrew Carnegie (1835–1919) was an ardent Spencerian, but his understanding focused (perhaps unsurprisingly) more on celebrating the worth of the successful than the inadequacy of the unsuccessful. To this end, he became a major philanthropist, funding public libraries in America and elsewhere in the world. His hope was that these institutions would be places where the poor-but-gifted could, through reading and education, rise up in the social scale.

Victorian thinkers took a variety of different routes in the name of evolution. Darwin’s fellow evolutionist Alfred Russel Wallace (1823–1913) was a lifelong socialist. Taking the opposite tack from Spencer, he used biology to justify a state welfare system. In his view the evolutionary struggle was between groups, not individuals; therefore people within the same society should band together and help each other. Russian prince and anarchist Pyotr Kropotkin (1842–1921) came from a tradition which saw a struggle less between people as individuals than between organisms and their environment. He therefore believed that biologically all organisms have a sense of caring, an urge to mutual aid, directed toward members of their own species; politically he translated this into anarchism.

THE TWENTIETH CENTURY

Social Darwinism fell out of fashion by the beginning of the twentieth century. A belief in progress, fundamental to the idea that biology was mirrored in the social world, had declined. It became apparent that despite advances in science and industry the world’s ills—poverty, disease, violence—persisted. The First World War made the optimism of the nineteenth century seem almost obscene. Coupled with this, more and more people saw something fallacious about equating evolution with behavior. Thomas Henry Huxley (1825–1895), an English biologist and advocate of Darwin’s theories, was eloquent on this subject, pointing out that what is moral often requires us to deny our animal heritage and go in a direction contrary to our evolved inclinations.

Nevertheless the ideas of Social Darwinian persisted, if not by that or any other name, transformed to suit the biology and social demands of the twentieth century. Julian Huxley (1887–1975), Thomas Henry’s grandson (and the older brother of Aldous, the novelist) believed that biology provides a guide to life showing that progress is a rule that runs through the world, from the living to the social and cultural. He had faith in the power of science and technology; arguing that true progress comes only when the state harnesses its energies and intelligence and uses them for the common good. He considered the Tennessee Valley Authority, which had brought power to millions of people, a paradigmatic example of progress in action.

There was a darker side to Social Darwinism. It has been implicated in the rise of National Socialism, and some think that evolutionary ideas, particularly as promoted by Darwin’s great German champion Ernst Haeckel (1834–1919), were significant. There may be truth in this last claim. Certainly, passages in Hitler’s *Mein Kampf* (1925) seem to be taken directly from popular accounts of Darwinism as applied to society in *On the Origin of Species*. But the history of German anti-
Semitism is too complex for a straight causal connection to be made. Apart from anything else, the Nazis hated the evolutionary idea that all humans are descended from monkeys and that biologically Aryans and Jews are not much different.

THE TWENTY-FIRST CENTURY
In the twenty-first century, Social Darwinism continues to influence public debate. Harvard entomologist and sociobiologist Edward O. Wilson has been a leader in arguing that biology must inform social policies. He believes that humans have evolved in a symbiotic relationship with other organisms, and that humans must cherish and promote biodiversity or die as a species. Linking Wilson strongly to the nineteenth century is a belief in progress, in both biology and society. For Wilson, the moral imperative to promote biodiversity flows from a belief that if humans become extinct, the highest life form on the planet will have vanished. He sees this in itself as a bad thing and a reason for action.

Throughout the centuries since its inception, Social Darwinism has meant different things to different people. Was it a good thing or a bad thing? As with most philosophies, that question has no simple answer. In the hands of some, Social Darwinism was a force for good, in other hands much less so. We can say that it was important as a social influence, and its underlying ideas persist today, although they often go by other names.

DATA
The word data (singular, datum) is originally Latin for “things given or granted.” Because of its humble and generic meaning, the term enjoys considerable latitude both in technical and common usage, for almost anything can be referred to as a “thing given or granted” (Cherry 1978). With reasonable approximation, four principal interpretations may be identified in the literature. The first three capture part of the nature of the concept and are discussed in the next section. The fourth is the most fundamental and satisfactory, so it is discussed separately in the subsequent section. Further clarifications about the nature of data are also introduced. A reminder about the social, legal, and ethical issues raised by the use of data concludes this entry.

THREE INTERPRETATIONS OF THE CONCEPT OF DATA
According to the epistemic (i.e., knowledge-oriented) interpretation, data are collections of facts. In this sense, data provide the basis for further reasoning—as when one speaks of data as the given of a mathematical problem—or represent the basic assumptions or empirical evidence on which further evaluations can be based, as in a legal context. The limits of this interpretation are mainly two. First, it is overly restrictive in that it fails to explain, for example, processes such as data compression (any encoding of data that reduces the number of data units to represent some unencoded data; see Sayood [2006] for an introduction) or data cryptography (any procedure used to transform available data into data accessible only by their intended recipient; see Singh [1999] for an introduction), which may apply to facts only in a loosely metaphorical sense. Second, it trades one difficult concept (data) for an equally difficult one (facts), when actually facts are more easily understood as the outcome of data processing. For example, census data may establish a number of facts about the composition of a population.

According to the informational interpretation, data are information. In this sense, for example, personal data are equivalent to information about the corresponding individual. This interpretation is useful in order to make sense of expressions such as data mining (information gathering; see Han and Kamber [2001] for an introduction) or data warehouse (information repository). However, two major shortcomings show its partial inadequacy. First, although it is important to stress how information depends on data, it is common to understand the former in terms of the latter, not vice versa: information is meaningful and truthful data—for example, “paper is inflammable” (Floridi 2003). So one is left with the problem of understanding what data are in themselves. Second, not all data are informational in the ordinary sense in which information is equivalent to some content (e.g., a railway timetable) about a referent (the schedule of trains from Oxford to London). A music CD may contain
gigabytes of data, but no information about anything (Floridi 2005).

According to the computational interpretation, data are collections (sets, strings, classes, clusters, etc.) of binary elements (digits, symbols, electrical signals, magnetic patterns, etc.) processed and transmitted electronically by technologies such as computers and cellular phones. This interpretation has several advantages. It explains why pictures, music files, or videos are also constituted by data. It is profitably related both to the informational and to the epistemic interpretation, since a binary format is increasingly often the only one in which experimental observations or raw facts may be available and further manipulated (collected, stored, processed, etc.) to generate information, for example, in the course of scientific investigations (von Baeyer 2003). Finally, it highlights the malleable nature of data and hence the possibility of their automatic processing (Pierce 1980). The main limit of this interpretation lies in the confusion between data and the format in which data may be encoded. Data need not be discrete (digital); data can also be analog (continuous). A CD and a vinyl record both contain music data. Binary digits are only the most recent and common incarnation of data.

Given these interpretations, it seems wise to exercise some flexibility and tolerance when using the concept of data in different contexts. On the other hand, it is interesting to note that the aforementioned interpretations all presuppose a more fundamental definition of data, to which we now turn.

THE DIAPHORIC INTERPRETATION OF DATA

A good way to uncover the most fundamental nature of data is by trying to understand what it means to erase, damage, or lose data. Imagine the page of a book encrypted or written in a language unknown to us. We have all the data, but we do not know the meaning, hence we have no information, facts, or evidence. Suppose the data are continuous pictograms. We still have all the data, but no binary bits. Let us now erase half of the pictograms. We may say that we have halved the data as well. If we continue in this process, when we are left with only one pictogram we might be tempted to say that data require, or may be identical with, some sort of representation. But now let us erase that last pictogram too. We are left with a white page, yet not without data. For the presence of a white page is still a datum, as long as there is a difference between the white page and the page on which something is written. Compare this to the common phenomenon of “silent assent”: silence, or the lack of perceivable data, is as much a datum as the presence of some rumor, exactly like the zeros of a binary system. We shall return to this point presently, but at the moment it is sufficient to grasp that a genuine, complete erasure of all data can be achieved only by the elimination of all possible differences. This clarifies why a datum is ultimately reducible to a lack of uniformity.

More formally, according to the diaphoric interpretation (diaphora is the Greek word for “difference”), the general definition of a datum is: (D) datum = x being distinct from y, where x and y are two uninterpreted variables and the domain is left open to further interpretation.

This definition can be applied at three levels: (1) Data as diaphora de re, that is, as a lack of uniformity in the world (Seife 2006). There is no specific name for such “data in the wild.” A possible suggestion is to refer to such data as dedomena (“data” in Greek; note that the word data comes from the Latin translation of a work by Euclid entitled Dedomena). Dedomena are not to be confused with environmental data. Dedomena are pure data or proto-epistemic data—that is, data before they are interpreted. Dedomena can be posited as an external anchor of information, for dedomena are never accessed or elaborated independently of a level of abstraction. They can be reconstructed as requirements for any further analysis: they are not experienced but their presence is empirically inferred from (and required by) experience. Of course, no example can be provided, but data as dedomena are whatever lack of uniformity in the world is the source of (what looks to information systems like us) data—for example, a red light against a dark background.

(2) Data as diaphora de signo, that is, as a lack of uniformity between (the perception of) at least two physical states of a system, such as a higher or lower charge in a battery, a variable electrical signal in a telephone conversation, or the dot and the dash in the Morse alphabet.

(3) Data as diaphora de dicto, that is, as a lack of uniformity between two symbols of a code—for example, the letters A and B in the Latin alphabet.

Depending on one’s interpretation, dedomena in (1) may be either identical with, or what make possible, signals in (2), and signals in (2) are what make possible the coding of symbols in (3).

The dependence of information on the occurrence of well-structured data, and of data on the occurrence of differences (dedomena) variously implementable physically, explains why information can so easily be decoupled from its support. The actual format, medium, and language in which data (and hence information) are encoded are often irrelevant and hence disregardable. In particular, the same data may be analog or digital, printed on paper or viewed on a screen, in English or in some other language, expressed in words or pictures, or quantitative or qualitative.
Interpretations of the support-independence of data can vary radically, for the definition (D) above leaves undetermined:

- the classification of the relata (taxonomic neutrality);
- the logical type to which the relata belong (typological neutrality);
- the dependence of their semantics on a producer (genetic neutrality).

We shall now look at each form of neutrality in turn.

**Taxonomic Neutrality** A datum is usually classified as the entity exhibiting the anomaly, often because the latter is perceptually more conspicuous or less redundant than the background conditions. However, the relation of inequality is binary and symmetric. A white sheet of paper is not just the necessary background condition for the occurrence of a black dot as a datum; it is a constitutive part of the (black-dot-on-white-sheet) datum itself, together with the fundamental relation of inequality that couples it with the dot. Nothing is a datum in itself. Rather, being a datum is an external property. This view is summarized by the principle of taxonomic neutrality (TaN): a datum is a relational entity.

The slogan is “data are relata,” but the definition of data as differences is neutral with respect to the identification of data with specific relata. In our example, one may refrain from identifying either the red light or the white background as the datum.

**Typological Neutrality** Five classifications of different types of data as relata are common. They are not mutually exclusive, and the same data may fit different classifications depending on the circumstances, the type of analysis conducted, and the level of abstraction adopted.

Primary data are the principal data stored in, for example, a database. Such data may be a simple array of numbers. They are the data an information-management system is generally designed to convey (in the form of information) to the end user. Normally, when speaking of data one implicitly assumes that primary data are what is in question. So, by default, the flashing red light of the low-battery indicator is assumed to be an instance of primary data conveying primary information.

Secondary data are the converse of primary data, constituted by their absence. Clearly, silence may be very informative. This is a peculiarity of data: their absence may also be informative.

Metadata are indications about the nature of some other (usually primary) data. Metadata describe properties such as location, format, updating, availability, usage restrictions, and so forth. Correspondingly, metainformation is information about the nature of information. The statement “‘Rome is the capital of Italy’ is encoded in English” is a simple example.

Operational data are data regarding the operations of the entire data system and the system’s performance. Correspondingly, operational information is information about the dynamics of an information system. Suppose a car has a yellow light that, when flashing, indicates that the car-checking system is malfunctioning. The fact that the light is on may indicate that the low-battery indicator is not working properly, thus undermining the hypothesis that the battery is flat.

Derivative data can be extracted whenever data are used as indirect sources in a search for patterns, clues, or inferential evidence about something other than that directly addressed by the data themselves, as in comparative and quantitative analyses. Derivative data are used, for example, when one infers a person’s whereabouts at a given time from her credit card data and the purchase of gasoline at a certain gas station.

Let us now return to the question of whether or not there can be dataless information. The definition of data given above (D) does not specify which types of relata are in question, only that data are a matter of a relation of difference. This typological neutrality is justified by the fact that, when the apparent absence of data is not reducible to the occurrence of negative primary data, what becomes available and qualifies as information is some further non-primary information $x$ about $y$ constituted by some non-primary data $z$. For example, if a database query provides an answer, it will provide at least a negative answer—for example, “no documents found.” This datum conveys primary negative information. However, if the database provides no answer, either it fails to provide any data at all, in which case no specific information is available (so the rule “no information without data” still applies) or it can provide some data to establish, for example, that it is running in a loop. Likewise, silence, this time as a reply to a question, could represent negative primary information such as implicit assent or denial, or it could carry nonprimary information—for example, about whether the person heard the question or about the level of noise in the room.

**Genetic Neutrality** Finally, let us consider the semantic nature of the data. How data can come to have an assigned meaning and function in a semiotic system is the first place is one of the hardest problems in semantics. Luckily, the question is not how but whether data constituting information as semantic content can be meaningful independently of an informee. The genetic neutrality (GeN) principle states that: GeN data can have a semantics independently of any informee.
Before the discovery of the Rosetta stone in 1799, ancient Egyptian hieroglyphics were already regarded as information, even if their semantics was beyond the comprehension of any interpreter. The discovery of an interface between Greek and Egyptian did not affect the semantics of the hieroglyphics, but only its accessibility. This is the weak sense in which meaningful data may be embedded in information-carriers informee-independently. GeN supports the possibility of information without an informed subject, and it is to be distinguished from the stronger, realist thesis (supported, for example, by Dretske [1981]), according to which data could also have their own semantics independently of an intelligent producer/informer.

CONCLUSION

Much social research involves the study of logical relationships between sets of attributes (variables). Some of these variables are dependent; they represent the facts that a theory seeks to explain. Other variables are independent; they are the data on which the theory is developed. Thus, data are treated as factual elements that provide the foundation for any further theorizing. It follows that data observation, collection, and analysis are fundamental processes to elaborate a theory, and computational social science (high-performance computing, very large data storage systems, and software for fast and efficient data collection and analysis) has become an indispensable tool for the social scientist. This poses several challenges. Some are technical. For example, data may result from a variety of disparate sources (especially when collected through the Internet) whose reliability needs to be checked; data may be obtainable only through sophisticated processes of data mining and analysis whose accurate functioning needs to be under constant control; or the scale, complexity, and heterogeneous nature of the dataset may pose daunting difficulties, computationally, conceptually, and financially. Other challenges are intellectual, ethical, political, or indeed social. Some of the main issues that determine the initial possibility and final value of social research include quality control (e.g., timely, updated, and reliable data); availability (e.g., which and whose data are archived, and using what tools); accessibility (e.g., privacy issues and old codification systems or expensive fees that can make data practically inaccessible); centralization (e.g., economy of scale, potential synergies, the increased value of large databases); and political control (e.g., who exercises what power over which available datasets and their dissemination).

Data are the sap of any information system and any social research that relies on it. Their corruption, wanton destruction, unjustified concealment, or illegal or unethical use may easily undermine the basic processes on which not only scientific research but also the life of individuals and their complex societies depend (Brown and Duguid 2000). In light of the importance of data, their entire life cycle—from collection or generation through storage and manipulation to usage and possible erasure—is often protected, at different stages, by legal systems in various ways and in many different contexts. Examples include copyright and ownership legislation, patent systems, privacy-protection laws, fair-use agreements, regulations about the availability and accessibility of sensitive data, and so forth. The more societies develop into databased societies, the more concerned and careful they need to become about their very foundation. Unsurprisingly, since the 1980s, a new area of applied ethics, known as information ethics (Floridi 1999), has begun to address the challenging ethical issues raised by the new databased environment in which advanced societies grow.

DATA, LONGITUDINAL

To understand the characteristics and uses of longitudinal data, it is first important to understand what cross-sectional data are. Social science researchers have used cross-sectional data, which are drawn from surveys of samples of individuals or groups (aggregate data), to investigate the differences or differentiations among the individuals or groups. Unlike longitudinal data, cross-sectional data collect information only one time. As with cross-sectional data, longitudinal data may be used to understand differences among individuals. If repeated, the cross-sectional data could be considered a subset of longitudinal data. However, the major purpose of gathering longitudinal data is to investigate the changes within the samples over a period of time, from a few months to several decades (life-course studies). Researchers explore many different aspects of longitudinal data, including the distribution of values, temporal trends, anomalies, and the relationship between multiple responses and covariates in relation to time.

Researchers who make use of longitudinal data are often most interested in the changes within individuals while considering the changes of other relevant variables, such as ecological changes, situational factors, changes of social interaction over time, and/or developmental life stages. For example, in 1997 the Panel Study of Income Dynamics that updated the sample combinations (representative data for the current population in the United States) was intended to collect detailed information about economic and social disparities in child development on a national scale. A follow-up wave of the same subjects was conducted in 2002. As presented by Robert Mare and Margot Jackson in their 2004 article, researchers used these data to investigate how residential mobility and neighborhood change contribute to the overall socioeconomic variation in children’s neighborhoods.

Criminologists use longitudinal data to survey trends in substance use (or other deviant behaviors) within a cohort or individual substance use (or other deviant behaviors) over time. Sociologists have used the National Longitudinal Youth Survey, a longitudinal study that presents self-reports of deviant and illegal behavior from the initial wave of 1976 to the 2003 wave (with data collection ongoing); it also presents other variables relevant to families, schools, and peer association, aiding sociologists in their investigation of the life cycles of families, immigration mobility, and their consequences. The political scientists Michael Delli Carpini and Scott Keeler (1991) used the U.S. censuses over a period of decades to determine whether contemporary U.S. citizens were better or more poorly informed about politics than were citizens of earlier generations. These studies are also referred to as pseudo-panel studies because they try to investigate the changes over time in a certain population, while subjects are chosen independently each time. In other words, such studies are not the same as the narrowly defined longitudinal studies. Nevertheless, some researchers may view them as such. The social psychologists Howard Kaplan and Cheng-Hsien Lin (2000) investigated whether the link between mental health and deviance is reciprocal or unidirectional by repeatedly surveying the same subjects and, more important, whether both variables covariate over time. This study especially took advantage of the causal implications indicated by longitudinal data to resolve confusion over causal direction suggested by theories.

ADVANTAGES AND DISADVANTAGES

Longitudinal datasets provide several advantages over cross-sectional data. First, such datasets can track the changes among subjects over a short or a long period of time. Social scientists use such data to explore the potential trends underlying social mobility and unexpected trends in a society. Second, longitudinal datasets indicate the nature of covariates among variables over time to clarify their relations. In other words, controlling the previous measures of these variables helps social scientists determine the strength of relations among them. Third, the causal relations between variables can be verified through a clear time sequence of these variables. Researchers can examine many factors, such as deviant peer association and deviant behavior, with regard to their theoretical reciprocal relations only by using longitudinal data analysis. Finally, longitudinal data can indicate developmental (life stages) and historical trends; cross-sectional data can only partially indicate or describe developmental trends because the influences of confounding effects of historical trends cannot be taken into account in the analysis.

Nevertheless, longitudinal data are collected at high cost. First, because they require at least two waves, the cost of their collection is much higher than that of cross-sectional data in terms of both labor required and economic demands. Second, if the initial wave of a dataset was biased for any reason, the follow-ups will amplify the bias because of the repeated survey of the sampled subjects. Third, repeat respondents may develop a pattern of response attitudes to make every follow-up interview easier, which may lead to invalid responses (an effect known as panel conditioning). The developing pattern of interactions between an interviewer and an interviewee may also result in invalid responses. For example, an interviewer may learn that subjects would like to avoid certain sensitive questions, so, to avoid unpleasant confrontations, the interviewer may assume that the subject would give the same or a similar reply as in the earlier sessions of the interview.
Finally, if researchers use a type of longitudinal data collection known as panel study design, panel attrition because of death and/or withdrawal of some participants may bring unexpected bias to the data analyses. For example, studies that collect data about delinquent behavior among juveniles may lose some of the more serious delinquents in the first wave if they in fact become criminals, are arrested and imprisoned, or die from their criminal activities. Such first-wave respondents are less likely to hold a long-term job and thus will be difficult to locate for future interviews. It is not surprising that these subjects are quite different from the rest of the samples. Conclusions to be drawn from analyses of the longitudinal data are thus at risk.

TYPES OF LONGITUDINAL STUDIES

Longitudinal data have different forms. Trend studies use the same measurements to investigate samples of a society at intervals to see if the society has held certain attitudes or values over time. Such studies survey different sampled groups in every wave of data collection and then compare the changes. Research on political preferences in different decades often makes use of trend data. A potential problem in trend studies is the possibility of incomparable samples collected in different waves. For example, a common problem is that the sample interviewed in an early wave is less educated than the second wave because educational attainment tends to increase in subsequent generations. Since educational attainment is often closely related to other social and individual factors, the discrepancy in educational attainment between generations may make the data suggesting changing trends of certain social attitudes and values less credible.

Cohort data tighten the selection of samples by focusing on a cohort or a subpopulation in a society. Although it may sample different groups out of the whole population, every sampled group shares a common feature. They might have been born within a certain span of years or raised during a particular societal event, such as World War II or the civil rights movement. The analyses of cohort data provide information about how a generation’s attitudes may change over time. It avoids the problem of generational differences that are compounded by trend studies.

Panel data collect information from the same group of subjects over time and are intended to examine the changes within individuals specifically. Whereas in general trend data and cohort data indicate overall changes in the society or a studied subgroup, panel studies attempt to examine how each subject’s attitudes and behaviors changed individually over the studied years. The most serious problem in collecting panel data is sample attrition, but this method provides the most comprehensive data on change. Researchers must be aware of the risk when drawing conclusions based on their studies.

Longitudinal data have grown in popularity among social scientists since the 1970s, becoming the mainstream in the 1990s. New, convenient statistical programs dealing with time-series analysis, latent growth curve models, hierarchical linear models, event history analysis, and structural equation models have greatly aided researchers using panel studies in clarifying relations among psychological and behavioral variables. Most likely, the scientific benefits of longitudinal data will make them the dominant data form.

DATA, PSEUDOPANEL

Among all sociological research designs, longitudinal studies are the best choice if the purpose of research is to examine changes over time. Cross-sectional studies observe a phenomenon at only one point in time, and
causal relationships between independent and dependent variables in cross-sectional studies are unclear because the time sequences cannot be established. There are three special types of longitudinal studies usually adopted by researchers: trend studies, cohort studies, and panel studies. Of them, panel studies are the most difficult for researchers who are collecting data because they have to interview the same sample of subjects repeatedly. Trend studies and cohort studies can provide changes of attitudes or behaviors of a population, but they cannot detect changes in a subject, only overall changes of the studied samples.

Panel studies can eliminate such a problem by examining the same subjects over time; typically researchers find that overall changes remain stable (the number of subjects who change their responses from A to B is balanced by those who change their responses from B to A). Although this is a great advantage of panel studies, it has its shortcomings. Panel studies are costly in both time and money (due to the high number of interviewers and the expenses associated with interviews and traveling), especially in a large-scale survey across several regions or states. Moreover panel studies often have a common problem: sample attrition. Researchers must revisit these subjects for a long-term research project, and subjects may fall out of contact. In order to retain most of the advantages and avoid the disadvantages of panel studies as well as the limitations researchers sometimes encounter in obtaining sufficient supports for panel studies, pseudopanel studies may be the second-best choice.

Pseudopanel studies may take different formats. In one a researcher asks respondents about past and current attitudes or behaviors and then treats the data as if they represented different time points. Another format uses simple logic to infer the time order of two or more variables. For example, it is more likely that people have tried cigarettes before cocaine because smoking is more socially acceptable than using cocaine; criminological studies have supported this conclusion. Researchers use established causal relationships from prior studies to assume similar relationships in their current studies when adopting cross-sectional study design.

Although the pseudopanel study avoids some of the problems or difficulties of the panel study, it is not recommended unless a panel study design is not accessible. Pseudopanel study is vulnerable to its own problems. For one, people’s faulty memories are hard to detect and not uncommon for many reasons. Subjects may sincerely forget things that occurred in their pasts due to poor memory, or they may lie about their pasts for various reasons. In addition the use of logical inferences depends on the researchers’ knowledge of the research topic. An expert might have a strong knowledgeable background to make robust inferences, but still that might not rule out the potential errors of pseudopanel study design.

**DATA ENVELOPMENT ANALYSIS**

Data Envelopment Analysis (DEA) is a technique relying on mathematical programming methods for estimating various types of efficiency in production. First applied by Michael Farrell in 1957, the technique was popularized and named by Abraham Charnes, William W. Cooper, and Eduardo Rhodes in the late 1970s. As of 2004, more than 1,800 articles using DEA had been published (see Gattoufi et al. 2004).

Standard microeconomic theory of the firm describes a production set containing all feasible combinations of input quantities and output quantities for a given industry. Firms operating on the upper boundary of this set are technically efficient, while firms operating below the upper boundary are technically inefficient. Technically efficient firms may be allocatively inefficient if they do not use the optimal mix of inputs (determined by input prices) to produce the optimal mix of outputs (determined by output prices). Technically inefficient firms can feasibly reduce the quantities of inputs used without reducing output quantities, increase output quantities without increasing input quantities, or simultaneously reduce input quantities while increasing output quantities.

Various measures of efficiency have been defined, and, in each case, efficiency depends on the firm’s location within the production set. Given observations on pairs of input and output quantities, DEA estimates the unknown production set using a convex set determined by the data. As a practical matter, DEA efficiency estimates are usually computed by solving a linear program.

The usefulness of DEA lies in its ability to estimate efficiency when multiple inputs are used to produce multiple outputs, without the need to specify distributions or
functional forms. DEA is a fully nonparametric estimation method. For estimating technical efficiency, DEA does not require information about prices, making it especially useful in many public-policy applications, where economically meaningful prices often do not exist. These features contrast with parametric approaches, where distributions for random variables reflecting noise and inefficiency, as well as a functional form (e.g., translog) for the response function, must be specified. The nonparametric nature of DEA means that it is very flexible and can potentially be used to describe a wide variety of situations.

Unlike parametric approaches, however, DEA makes no allowance for noise or measurement error, which can severely distort DEA efficiency estimates. A number of outlier-detection techniques have been developed for use with DEA estimators (e.g., Wilson 1993; Simar 2003; Porembski et al. 2005). In addition, researchers have recently introduced new estimators that retain the nonparametric feature of DEA but are resistant to the effects of outliers and related problems.

Until recently, the statistical properties of DEA estimators remained unknown, and methods for making inferences about efficiency using DEA estimators were unavailable. In 2000, Léopold Simar and Paul Wilson provided a survey of new developments. In particular, the convergence rates of DEA estimators depend on the numbers of inputs and outputs, or the dimensionality of the production set. These rates worsen with increasing dimensionality. Consequently, to retain the same order of magnitude in estimation error, sample sizes must increase exponentially as dimensionality increases. Computationally intensive bootstrap methods provide the only practical approach to inference with DEA estimators. Due to the boundary of the production set, standard bootstrap methods must be modified by smoothing procedures to yield consistent inference.

DAUGHTERS OF THE AMERICAN REVOLUTION

The Daughters of the American Revolution (DAR) is generally known as the oldest and largest women’s lineal descent-based patriotic organization in the United States. Although the DAR, often regarded as an innocuous social club, has not attracted much attention from scholars until recently, it played a significant role in the formation of modern U.S. nationalism and national identity, particularly during the first half of the twentieth century.

The DAR was established in October 1890 by a group of upper- and middle-class women in Washington, D.C., after their failed bid to join in the founding of a similar ancestral organization, the Sons of the American Revolution (SAR), in the previous year. Although the DAR’s membership was originally restricted to adult female (and white) descendents of those who had served in one capacity or another for the cause of American Independence, the group was quick to seek nationwide recognition and membership. The origins of this ancestral, patriotic organization are multifarious. During the late nineteenth century, increased immigration from South and East Europe, labor and agrarian conflicts, and American expansion overseas caused many people in the United States to question who they were. More broadly, the United States was at the time emerging as a modern nation state whose people were beginning to share a sense of American identity. The formation of national identity was
facilitated by improvements in mass communication and transportation, the growth of a national market and public schooling, and the increasing power of the state over people’s daily lives. It was against this backdrop that the DAR, despite its traditional hereditary exclusiveness, was simultaneously able to promote among the general public a rather modern, abstract vision of loyalty to the nation.

The constitution of the DAR mentioned three main objectives of the society: (1) to perpetuate the memory and spirit of the men and women who achieved American Independence; (2) to promote institutions of learning so that the young and old can develop the largest capacity for performing the duties of American Citizens; and (3) to cherish, maintain, and extend the institutions of American freedom and to foster true patriotism and love of country. Based on these ideals, the DAR engaged in various activities such as sponsoring historical restoration projects, distributing pamphlets to immigrants on how to become good American citizens, and publishing patriotic materials for schoolchildren.

The organizational motto of the DAR, “God, Home, and Country,” represented its proven political conservatism on issues like Christianity, gender and family relations, and communism. Yet a closer analysis of the DAR and its activities reveals some seeming contradictions, such as tolerance toward immigrants (who were seen as objects of Americanization) coupled with (until recently) exclusivist policies on many racial matters. Thus the DAR is best seen not just as a typical conservative organization but as a mirror reflecting the differentiating and hierarchical nature of modern nationalism.

DAVIS, ANGELA 1944–

Angela Davis established an early reputation as a scholar who linked race, class, and gender with activism. She became nationally known in 1970 when, after she was indicted for owning guns used in a courtroom shootout in California, she went underground. After a two-month search, the FBI arrested her in New York City. In those politically turbulent years, Davis became a highly visible prisoner, a symbol as an African American woman fighting for justice in prisons, and her imprisonment was protested across the nation and elsewhere in the world. She was acquitted of all charges in 1972.

Angela Davis was born in Birmingham, Alabama, on January 24, 1944; her father was a gas station owner, her mother a schoolteacher. Birmingham was a deeply racist city, referred to as Bombingham in the 1960s because of the many bombings of African American homes, businesses, and churches, but nevertheless even in the 1950s her mother and grandmother took her to protests. She attended segregated schools until high school, when she received a scholarship that allowed her to attend a private school in New York City. That experience provided further support for her developing political views, as she joined a socialist club and interacted with teachers with radical views. After high school she went to Brandeis University and attended the Sorbonne in Paris, where she developed a deeper understanding of political oppression in Algeria, which was under French control at the time, and began a political dialogue with Algerian students protesting French colonialism. While at Brandeis she studied with Herbert Marcuse, a radical philosopher. She graduated with honors from Brandeis with a major in French and then went to West Germany to study philosophy with Theodor Adorno, another radical intellectual. She went to Los Angeles in 1967 and began working with the Student Nonviolent Coordinating Committee, the Black Panther Party, and the Communist Party of the United States. She earned her master’s degree in philosophy in 1969 after completing all requirements for her dissertation except the dissertation and began teaching philosophy at the University of California at Los Angeles (UCLA).

In 1970, UCLA fired Davis because of her membership in the Communist Party, but she succeeded in convincing the courts to reinstate her. Soon thereafter she began work on the “Soledad Brothers” cause on behalf of inmates at California’s Soledad prison, which led to her indictment for gun ownership, her decision to go underground, and the FBI labeling her as a most wanted criminal. She returned to Germany to earn her doctorate at the Humboldt University of Berlin, and she taught at Stanford University, the Claremont Colleges, the

Davis, Jefferson

1808–1889

Jefferson Davis will always be associated with the Confederate States of America. There is a certain irony in this association. Although he was president of the Confederacy, Davis was not the “fire-eater” that South Carolina secessionist Rhett Barnwell Butler was. He did not favor immediate secession upon Abraham Lincoln's election to the presidency and in fact served on the Committee of Thirteen that fashioned the Crittenden Compromise select committee that attempted to compromise the Union back together again during the lame-duck congressional session of 1860–1861. He was not known for his public defenses of slavery or states rights, as another reluctant secessionist, James Henry Hammond, was. Davis’s major contribution to those debates was post hoc. He wrote The Rise and Fall of the Confederate Government (1881) well after the Civil War ended. As a prominent Mississippi planter, Davis had always supported slavery and states rights, but his association with those causes was forged during the war, not prior to it.

Prior to the war, Davis had a notable military and political career. He graduated from West Point in 1828 at the age of twenty. He served as an army officer until 1835, when he resigned his commission to marry his first wife and develop a plantation on land that his older brother had provided him. He also became active in Democratic politics. By the time he was elected to the House of Representatives in 1845, Davis was a wealthy cotton grower and slaveholder. At the outbreak of the Mexican War, he left Congress to serve as an officer in the Mississippi militia. Davis and his unit served with distinction at the Battle of Buena Vista. Upon his return to Mississippi in 1847, he was appointed and then elected to the United States Senate. In 1851 he resigned to unsuccessfully run for governor of Mississippi but he soon returned to Washington, D.C., as Franklin Pierce’s secretary of war. After the Pierce administration left office, Davis was again elected to the Senate. His final Senate term ended in January 1861, when Mississippi seceded from the union.

Davis was the first and only president of the Confederate States of America. As president of the Confederacy, Davis faced a number of military and political crises. The opinions of historians vary as to how successfully he met those crises but they almost invariably compare him unfavorably to his Union counterpart. Yet there are a number of parallels. Both Lincoln and Davis oversaw the creation of strong states that heavily taxed and conscripted their male citizens to pursue their war efforts. Both Lincoln and Davis involved themselves in day-to-day military decisions and seemed plagued by inept generals. Both Lincoln and Davis ultimately decided to...
recruit African-American soldiers, though, in Davis’s case, the war ended before the policy could be implemented.

At the conclusion of the war, Davis was among a number of Confederate leaders and generals who were imprisoned for treason. President Andrew Johnson eventually ordered all of them released except for Davis, whose case became entangled in impeachment politics. After Davis had been in military custody for two years, he finally appeared in civil court and was granted bail. The federal government eventually decided not to prosecute him. During the last twenty years of his life, Davis experienced financial difficulties and continuing ill health but his popularity in the former Confederate states never waned. By the time of his death, he had come to personify the South’s “lost cause.”

DAWES, ROBYN 1936–
Robyn Mason Dawes is the Charles J. Queenan Professor and former chair at the department of Social and Decision Sciences at Carnegie Mellon University. He received his PhD in mathematical psychology from the University of Michigan in 1963. Dawes’s work on human judgment and decision-making has influenced theory, research, and practice in diverse areas of psychology, including cognition, social behavior, and clinical assessment.

Inspired by Paul Meehl’s demonstration that simple statistical models outperform clinical judgment, Dawes showed that improper (i.e., unit-weight or even random-weight) regression models perform better than individual clinicians do as long as each predictor variable has some validity. Application of a linear combination formula yields reliable predictions, assuming the model’s user “knows how to add.” In contrast, intuitive judgments remain vulnerable to random errors and systematic biases. Although statistical prediction models promise to make judgments about people easy, efficient, and accountable, many practitioners continue to reject them, a resistance that has led Dawes to explore human irrationality more broadly.

Dawes’s analysis of human (ir)rationality is informed by Daniel Kahneman and Amos Tversky’s work on heuristics and biases. Although judgmental heuristics often yield correct predictions, they guarantee that some contradictions will also occur. One such contradiction involves a structural availability bias that seduces people to make frequency judgments about events they could not have observed. For example, clinical psychologists sometimes claim that certain problem behaviors never stop on their own without therapy, when they have no information about behavior outside of the therapeutic context.

Dawes’s focus on internal consistency as a criterion of rationality is narrower, but also more precise than competing definitions of rationality in terms of evolutionary or ecological adaptiveness. Dawes identifies the failure to make appropriate comparative judgments as a hallmark of irrationality. Often, people seek to understand surprising or distressing events retrospectively. For example, an airplane crash tends to stimulate reviews of other crashes in hopes that a cause can be found. To reach a valid conclusion, however, flights ending in crashes need to be compared with successful flights. The former analysis can only reveal what the flights of interest have in common, but it obscures crucial information about whether the rate of these common features is actually higher (or perhaps lower) than their rate in uneventful flights.

In Bayesian statistics, comparisons are expressed as likelihood ratios. For example, the probability of a plane crash given fog in the landing area is divided by the probability of a crash given the absence of fog. When multiplied with an event’s base rate, the likelihood ratio yields coherent predictions. Although base rate neglect is also a facet of irrationality, Dawes is mainly concerned with the human tendency to neglect the ratio’s denominator.

Nonetheless, Dawes is optimistic about people’s capacity to think rationally. His analogy is learning how to swim. Novices try to keep their heads above water at all times, which makes drowning more likely. Once they learn to keep their faces in the water, and to come up for air only intermittently, they “get it.”

Coherent judgments reduce the number of prediction errors, but they do not guarantee that outcomes will be desirable. Evil can be rational and banal, as a reading of the autobiography of Rudolf Höss, commandant at Auschwitz, suggests. If the premises are loathsome,

**DAY CARE**

*Day care* is a term that is commonly used in English-speaking North America. It refers to the care of young children by persons other than parents, guardians, or other close relatives (grandparents, for example) during a period when the children’s parents are not able to provide care. Typically, day care is associated with care for a child while the parent(s) are employed or participating in an educational program away from the home. (Programs such as preschools, nurseries, and kindergartens are typically part-time and less commonly associated with employment-related care.)

Day care takes a wide variety of forms, from what are termed “informal” arrangements (such as care in the home of a neighbor or friend, with no regulation by government), to more “formal” arrangements (such as care in a purpose-built facility with licensing by one or more levels of government). In most parts of North America informal care is more common than formal care. The numbers of children in care settings, the ages of those children, the number of adults present, the nature of activities provided in these settings, and the training of care providers vary significantly.

The care of children while their parents are employed outside the home has a lengthy history in Europe and North America. One of the very first programs to develop as a specific response to parental employment was the Infant Schools established in New Lanark, Scotland, in 1816. Robert Owen’s “Institution for the Formation of Character” was envisioned as much more than caregiving—it was an experiment in individual and broader societal development (Owen 1816). Infant schools moved beyond Scotland, and by the late 1820s similar programs could be found in North America, from Prince Edward Island to the Carolinas. However, by the late 1830s the infant school movement had died out in North America, an early victim of a complex interplay of ideologies, labor-force dynamics, class structures, immigration, social movements, and political positions that persist to the present. The public face of this dynamic was that “the mother’s place is in the home with her children”—an argument heard from the pulpit in the 1830s and a continuing force in day care debates today (Pence 1989).

As the labor force expanded in the late twentieth century to include an ever higher proportion of women,
including mothers, pressure mounted for governments, at both federal and state or provincial levels, to address the very significant and growing need for day care services through the establishment of funded and regulated systems of care. Adding to pressure felt by a changing labor force has been the strategic use of research on early childhood, including research on early brain development (Carnegie Task Force 1994; Shonkoff and Phillips 2000), to make a case for “high quality” care. These forces, augmented most recently by comparative studies of child care in other industrialized countries (OECD 2001, 2004), tipped the scales in Canada in early 2005, and the Liberal-led federal government committed $5 billion over five years toward the development of “high-quality developmental early learning and child care in collaboration with provinces and territories” (Governments of Canada and Manitoba 2005). When the Liberal government was defeated later that year, the new Conservative-led government withdrew support for the program. The sociopolitical dynamics of day care that arose in the early nineteenth century are still evident in the twenty-first century.

DEALIGNMENT

The term party dealignment refers to the erosion of party loyalties in an electorate. In theory, dealignment can occur in any electoral system, but the term is applied mostly to American politics. As used, here, it refers to the decrease in the percentage of American adults that identify either as Democrats or Republicans, and the corresponding increase in the percentage that identify as independents.

PARTY IDENTIFICATION AND ITS MEASUREMENT

Party identification is an individual’s psychological attachment to one or another of the major political parties. Those who identify as Democrats or Republicans are referred to as party identifiers, while those who decline to declare themselves either Democrats or Republicans are referred to as independents. Pollsters generally use a seven-point scale to measure party identification. The American National Election Studies (ANES) asks survey respondents, “Generally speaking, do you think of yourself as a Republican, Democrat, an independent, or what?” Next, Republican or Democratic identifiers are asked whether they identify strongly or not so strongly with their party, while independents are asked whether they lean toward one party or the other. Based on responses, pollsters then place respondents along a 7-point scale (1: Strong Democrat; 2: Weak Democrat; 3: Independent Democrat; 4: Independent Independent; 5: Independent Republican 6: Weak Republican; 7: Strong Republican).

DEALIGNMENT AND ITS CONSEQUENCES

In the American electorate, dealignment occurred primarily between the 1960s and 1990s. The political scientist Marjorie R. Hershey describes the process as follows:

In the 1950s and early 1960s, many more Americans called themselves Democrats than independents or Republicans. The Democratic edge began to erode after 1964, but Republicans were not immediately able to capitalize on the Democrats’ losses. In fact, the proportion of Republican identifiers declined from 1964 through the 1970s, even when a Republican president, Richard Nixon, was elected in 1968 and re-elected by a landslide in 1972. Democrats retained control of Congress, split-ticket voting was fairly common, the proportion of “pure independent” identifiers increased, and there was a steady stream of independent and third-party candidates. These changes in partisanship struck many scholars as resembling a dealignment, or decline in party loyalties. (2006, p. 133)

Party identification data indicate the trend well. The share of Americans identifying as either pure independents or independent “leaners” increased from 23 percent in 1952 to around 33 percent during the 1980s, to 40 percent in 2000, and remained nearly steady at 39 percent.
in 2004 (Hershey 2006, p. 325). However, further examination of the data also suggests that the share of Americans identifying as “pure” independents has decreased since the 1990s, while the share identifying as strong partisans, independent Democrats, and independent Republicans has also increased. Some political scientists argue that this indicates a renewed partisan polarization in the American electorate.

The consequences of dealignment include an increase in split-ticket voting (voting for different parties’ candidates for different offices) and lower voter turnout. Party identification is the single most important influence on voting, and as fewer Americans identify with a major party, straight-ticket voting (for candidates of only one party) becomes less attractive and Americans are more likely to support different parties’ candidates for different offices. Similarly, party identification simplifies voting decisions. But as more Americans identify as independents, they lose the easy voting cues that identification with a major party provides. Thus, more Americans must invest time and energy in researching and forming impressions of individual candidates, office by office. For some, the costs of this are too high, and voter turnout is likely to decline as a result.

DEALIGNMENT VERSUS REALIGNMENT

Party dealignment is a distinct concept from realignment. While dealignment means an erosion of party loyalties, realignment refers to an enduring shift in loyalty from one major party to the other among large numbers of voters. Further, this usually occurs in large enough numbers to create a new and lasting partisan majority. Thus, the 1896 election marked a partisan realignment that created a Republican majority in American politics that lasted until 1932. That year, perceived Republican inadequacies in addressing the Great Depression forged a Democratic majority in national politics that lasted until 1968.

In 1968, controversies over race relations, the Vietnam War, and the increasing importance of cultural issues contributed to partisan dealignment. During the 1970s and 1980s, that dealignment eroded Democratic dominance, but the number of independents increased much more than the number of Republicans did. More recently, other factors, including the realignment of white southerners toward the Republican Party and the renewed focus on national security issues after the September 11, 2001, attacks, contributed to Republican gains in party identification. In 2004 the share of Americans identifying as Democrats and Republicans was identical (at 33 percent) for the first time since the advent of modern polling.

DEATH AND DYING

Death is as much a cultural reality as it is a biological one. The only creature known to be aware of its inevitable demise, humans have dealt with their unique insight with considerable creative ritual and belief. Many have argued that religion, philosophy, consumerism, and even civilization itself were all created as antidotes to this terrifying insight (Becker 1973). Mythologist Joseph Campbell (1904–1987) hypothesized that mythmaking began with the first awareness of mortality, forcing early humans to seek purpose, to rationalize the irrational, and to deny death’s finality. Perhaps it should thus be of no surprise that much of what we know of past cultures is based on funerary artifacts—their attempts at death transcendence. A culture’s death system, or death ethos, determines such widely ranging phenomena as a people’s militancy and suicide rate; their preferences for bullfights, gladiator battles, or horror movies; their fears of or hopes for reincarnation and resurrection; their willingness to perform organ transplants or purchase life insurance; their decisions to bury, cremate, or eat their dead; and their attitudes toward capital punishment, abortion, and what constitutes a “good death.”

Cultures have been classified in terms of their death systems, shedding light on the meanings they give to life. Historian Arnold Toynbee (1889–1975), for example, categorized cultures by whether they are death-accepting or death-denying, hold a hedonistic or pessimistic view
toward life, perceive death to be the end of existence or a transition to some personal or collective form of immortality, view corpses as sacred or profane objects, and whether or not the dead are believed to play an active role in the affairs of the living (and whether in a positive or negative way). In the death-defying West, for instance, strategies for salvation have historically featured activism and asceticism, whereas in the East they have often been more contemplative and mystical. In the West, postdeath conceptions typically involve the integrity and continuity of one’s personal self; in the East, the ultimate goal is often an undifferentiated and impersonal oneness with the universe.

Changes in social solidarities (i.e., urbanization, religious pluralism), in selfhood (i.e., the shift from collectivist to individualistic identities), and in who dies and why, have historically produced several recognized epochs in the West, each featuring distinctive conceptions of death and funerary ritual. For most of human history, when life was short and “death in the midst of life” was a literal and not a figurative notion, cultural rituals and social systems were oriented to this fact. People were constantly reminded about time’s invariable passage and their inevitable mortal fate. Ancient Egyptians would have skeletons brought to their feasts; colonial Americans would daily walk past their church cemeteries, whose tombstones were adorned with skulls and crossbones. Death was “tame,” according to social historian Philippe Ariès (1914–1984). Deathbeds were community gathering places; public meeting spaces were often adjacent to mass graves whose contents were often partially visible. In early colonial America, realizing that two or three of their children would not survive until age ten, Puritan parents would send their offspring to family and friends as apprentices to avoid excessive attachments with them and the grief their deaths would cause (Stannard 1977).

According to Ariès, the contemporary era in the West features death denials and “invisible death,” fueling the illusion of immortality with institutions that conceal the dying (over 70 percent of Americans currently die within institutionalized settings) and that make the dead appear lifelike for funerary services. Those most likely to die are the old (nearly eight in ten deaths in the United States are those sixty and older), who are largely disengaged from many of their roles and physically segregated from other age groups in retirement communities and long-term care facilities. Gerontophobia, or fear of aging, has become interwoven with cultural thanatophobia, the fear of death.

So great is the power of an ethos, this construction of meaning thrown up against the terror of death, that social agencies invariably seek to harness its energy as a means of social control—and to enhance the social status of their members. For instance, consider religion’s traditional threats of agonizing hells or bad reincarnations as a means for keeping the living in line. The power and status of the medical establishment increased dramatically during the last century with its growing ability to postpone death. Because of scientific breakthroughs, modern medicine has largely eliminated many traditional causes of premature death, especially infectious disease, and the medical establishment competes with religion’s traditional control over the dying process. Accordingly, death is shifting from being a moral rite of passage to a technological one. Traditional fears of postmortem judgment are morphing into fears of dying; those most likely to die, the old, fear being institutionalized within nursing homes more than they fear death.

With most premature death now the result of man-made and hence theoretically avoidable causes (e.g., accidents, homicides, and suicides), its occurrence has become increasingly tragic and highly politicized. Political rulers have long enforced their control through death squads, pogroms, war, capital punishment, and campaigns of fear. Disdaining such strategies, modern regimes instead establish legitimacy and citizen loyalty by thwarting (or at least predicting) the death threats of enemies with the country’s military forces, of lethal microbes with health care systems, of violent storms with weather satellites, of possible earthquakes or volcanic eruptions with seismic monitoring stations, and of potential asteroid or meteor collisions with telescope arrays.

Some of the most contentious moral debates in the contemporary United States center on the right to end life (e.g., capital punishment, physician-assisted suicide, and civilian casualties in military campaigns) and precisely where the line between life and death occurs, as in the controversies over abortion and euthanasia.

Materialism, individualism, secularism, and the distractions of consumer and popular cultures have not eliminated individuals’ fears of death nor their desires to transcend it. The proportion of Americans believing in an afterlife has generally increased over recent decades, with more than seven in ten confident that their existence does not conclude with death. At a minimum, cultural death systems promise at least symbolic immortality (Lifton 1979), such as being remembered through one’s progeny or works of art, or surviving through the preservation of political or natural orders. Thus we witness the proliferation of such projects as halls of fame, the Social Security Administration’s online database of deceased Americans, and Forbes magazine’s annual ranking of top-earning deceased celebrities.

DEBREU, GERARD

1921–2005

Gerard Debreu, a French-born American mathematical economist and 1983 Nobel laureate, was a major force in the advancement of the theory of general equilibrium. His early influence came from the 1988 French Nobel laureate, Maurice Allais, who introduced him to the writings of Leon Walras (1834–1910), the founder of the mathematical theory of general equilibrium analysis.

In 1949 Debreu visited several premier universities, including Harvard and the University of California, Berkeley, on a Rockefeller fellowship. Following the fellowship, he spent a decade with the Cowles Commission, then attached to the University of Chicago, working on Pareto optima, the existence of a general economics equilibrium, and utility theory. Subsequently, after one year at Stanford, he moved to Berkeley in 1962 where he remained until his retirement in 1991. Besides mathematics, Debreu was so taken by the U.S. rule of law during his lectures his eyes would light up when he demonstrated the superiority of mathematical reasoning. He used to say that mathematical economists have the best of two worlds—their youth and economic discoveries when they are young and economic discoveries when they are old.

BIBLIOGRAPHY

Debreu's research interest was general equilibrium analysis, in line with Walras, whose method was to equate equations and unknowns. The essential idea is to show how prices gravitate from disequilibrium to their natural or equilibrium levels. Debreu liberated the analysis by opting for fixed-point and convex tools for general equilibrium analysis.

Convexity requires that the production and consumption sets be bowl-shaped. Debreu would “slip a hyperplane,” as he would say, through the tangent of those convex sets. He first revealed a proof at the 1950 meeting of the Econometric Society at Harvard that did not use the convexity solution. Many optimal solutions of the Pareto type and some possible competitive solutions resulted where prices are given and agents maximize their affairs. In 1954, in collaboration with Kenneth Arrow and using topological methods, which Debreu had used previously, he proved the existence of general equilibrium in an “epoch-making” paper, “Existence of an Equilibrium for a Competitive Economy.”

Debreu’s early book, The Theory of Value (1959), produced the hard-core ideas of his lifetime research program. He expressed the economy as

\[ \xi_j \left[ p \cdot \omega_j + \sum_{j=1}^{n} \theta_j \pi_j(p) \right] \]

where each consumer, \( i = 1 \ldots m \), has an initial endowment, \( \omega_j \), a share of the \( j \)th producer's profit, \( \theta_j \), and an underlying utility function for his or her preferences. Each producer, \( j = 1 \ldots n \), takes the prices that are announced, and maximizes profits, \( \pi_j \). The inner-bracketed terms represent the consumer budget from the initial endowment and shares of profits. Consumers will maximize their utility subject to their budget constraints, yielding demand functions. Excess demand functions are now possible by summing all the demand functions less endowment. Thus we can derive the equilibrium prices from the excess demand functions, which in two dimensions are usually the zeros or solutions of a quadratic equation.

Debreu built his theories on axioms, where a primitive such as a commodity becomes a mathematical object with spatiotemporal and physical characteristics. He urged his students to be concise, mentioning that John Nash demonstrated the equilibrium for finite games on only one page. During his lectures his eyes would light up when he demonstrated the superiority of mathematical reasoning. He used to say that mathematical economists have the best of two worlds—mathematical discoveries when they are young and economic discoveries when they are old.

Decentralization

Decentralization is the transfer or sharing of decision-making power from a central authority toward lower-level units or the end users. Decentralization signifies the disbursement of power from the top down within any type of organizational hierarchy, such as political, educational, or economic systems. The literature on political economy suggests that a greater degree of decentralization leads to higher levels of efficiency in the distribution of public resources and is associated with the use of locals’ own resources to address local needs and issues.

There are various types of governmental decentralization, depending on the constitutionality granted to lower-level units of government. Federalism is an arrangement in which different levels of the government enjoy constitutionally designated power and functions. The central authority in a federal system exists when lower-level units decide to enable the national government to have overseeing powers. In the United States, authority at the national government does not preclude the political rights that reside at the state level. The fifty states exercise their own taxing and spending authority and maintain primary control over their own affairs (such as public education). The national government does play an important role in federalism. It can allocate its centrally collected resources to address regional disparity and to provide services that benefit several subnational units, such as environmental protection.

Unitary governments, whose lower-level units may not enjoy constitutional guarantees of autonomy, can reallocate their power within the administrative and territorial system. In Great Britain, for example, regional autonomy exists in Northern Ireland, Wales, and Scotland, and the national government grants municipal autonomy to London. Although it can be repealed by the British Parliament and the monarchy, the complex system of elected local governments constitutes an integral part of the British political system. In other unitary systems, territorial decentralization is constitutionally provided for, and the powers of locally chosen officials are prescribed. The Japanese constitution, for example, specifies certain autonomous functions to be carried out by local administrative authorities.

Another governance arrangement may involve a hybrid of central supervision and local control. A good example is France. Until March 1982, when a law on decentralization was enacted, the French administrative system was constructed around departments, each directed by a prefect, and subdivided departments, each directed by an underprefect. The prefects and the underprefects were appointed by the national government in Paris to act as agents of the central government and also as the directors of the regional governments, which included locally elected officials. That system combined central supervision of local affairs through appointed officials with territorial representation through locally elected governmental bodies.

The degree of decentralization, to be sure, involves trade-offs in governmental functions and political power. A decentralized system of governance is likely to implement fiscal policy based on the “benefits-received” principle, where local taxpayers receive locally funded services. This practice may lead to intercommunity competition for private capital and productive workers, as they form the basis of a sound local economy.

A race to the bottom can occur as power is decentralized to municipalities. To enhance their competitiveness, local governmental units tend to reduce locally funded social welfare services and to relax labor and environmental regulations as much as possible to lure economic investment. In developing economies, for example, communities that offer the least costly workforce tend to attract foreign capital. In putting into practice the notion...
of cost-reducing scale economies, companies prefer lower overhead costs with lower local taxes and greater discretion over wages.

At the same time, a centralized system may make allocative decisions that do not necessarily reflect local and regional needs to the extent that the system functions at a suboptimal level. In other words, a mix of decentralized decision-making and centralized coordination is necessary to promote efficiency and fairness.

**DECISION-MAKING**

Standard models of decision-making hold that rational agents maximize expected utility. These models presuppose a notion of rationality that is substantive (i.e., that involves making choices that have certain substantive outcomes, such as maximizing expected utility) and forward-looking (i.e., that is solely a function of future costs and benefits). Despite the fact that this notion of “utility” is notoriously vague, utility maximization theories have a formal clarity and precision. Unfortunately, they also make highly idealized assumptions about decision-makers—namely that they are superhuman probability calculators whose preferences are precisely and stably ordered.

Since the 1950s, economists and psychologists have moved away from forward-looking, substantive theories of rationality, and toward procedural theories of rationality. Procedural theories take rationality to involve making choices in accordance with certain rules or processes, and these rules or processes are typically grounded in psychologically realistic accounts of decision-making. This focus has led to an explosion of research into decision-making in business, government, and the marketplace. Much of the groundbreaking work in this area was done by Amos Tversky and Daniel Kahneman (Kahneman won the Nobel Prize for Economics in 2002 for his research on the economics of choice).

**AUTOMATIC VS. DELIBERATIVE PROCESSES**

While the paradigm case of decision-making is voluntary and deliberative (e.g., selecting a new car or a retirement plan), many cognitive processes are involuntary and automatic. Some automatic decision-making seems to occur in a perception-like system. These “System 1” processes are fast, automatic, parallel, effortless, associative, and emotional. “System 2” processes, on the other hand, are slow (in the deliberative sense), serial, controlled, effortful, rule-governed, flexible and emotionally neutral. Reasoning is a characteristic System 2 process. Which system is being used can be determined by an effort diagnostic: System 2 processes are easily interfered with by a simultaneous activity.

System 1 processes include impression formation, one-on-one communication, and much group behavior. John Bargh’s work shows that much of our social behavior (e.g., nose-scratching) is imitative, triggered automatically by an activation of the motor cortex. Consumer choice, memory for events, mathematical skills, and hostility for others are regulated by automatic processes that people are largely unaware of, and which can be triggered by environmental features to which people pay no explicit attention. For example, music in a store can reduce the shopper’s blink rate from the normal average of thirty-two times a minute to a hypnotic (and suggestible) fourteen blinks a minute (Smith and Curnow 1966).

**FRAMING EFFECTS**

Framing effects occur when messages carrying the same statistical information cast in different ways prompt different behavior. If someone who tests positive for HIV or
breast cancer has a 70 percent chance of living beyond seven years, then that person has a 30 percent chance of dying within seven years. But these messages have different impacts. In 2001, Tamera Schneider and colleagues created gain-framed videos that explained the positive effects of healthful behavior and regular breast exams, as well as loss-framed videos that attempted to frighten viewers with the potential negative consequences of not seeing a doctor. Subjects in the gain-framed message condition were significantly more likely to arrange mammograms. In a 2003 paper, Anne Marie Apanovitch, Danielle McCarthy, and Peter Salovey showed that message framing also motivates subjects to get tested for HIV.

THE FUNDAMENTAL ATTRIBUTION ERROR
When observing the behavior of others, people tend to overattribute behavior to dispositional factors, such as motives, capacities, and personality traits. They also tend to underestimate the causal influence of situational factors, such as whether the subject is pressed for time or is in an uncomfortably warm room. This “fundamental attribution error” (FAE) has proved both stable and resistant to correction. Interestingly, however, Incheol Choi and Richard Nisbett found in 1998 that Koreans are significantly less susceptible to the FAE than Americans.

The FAE leads to the actor-observer effect, where people tend to explain their own behavior in terms of situational factors, while other people’s behavior is explained in terms of dispositional factors. A noteworthy consequence of the actor-observer effect is that people tend to explain other people’s economic successes or difficulties in terms of behavioral and dispositional factors. They tend to explain wealth in terms of hard work and wise decisions, but rather than explain poverty in terms of the situations of those suffering, it is often explained with derogatory attributions. In other words, it is often believed that people are poor because they are lazy, stupid or ignorant. Situational factors are, however, thought to exert a potent influence on social behavior.

AFFECTIVE FORECASTING
A number of studies that allow subjects to predict how some event will affect their life or the lives of others have confirmed that people are not good at tracking the impact and duration that events will have on our lives. There is a wide gulf between what people believe makes them happy and what actually does make them happy. Events that are predicted to be devastating, such as getting denied tenure, and those thought to make one happy, such as gaining tenure or winning the lottery, often have no lasting impact on human happiness (see Gilbert, et al. 1998; Brickman et al. 1978). It may be difficult for people to admit, but affective forecasting—the psychological process of predicting how one will react to life events—cannot be trusted (see Wilson and Gilbert 2003). As Kahneman et al. put it, “People are unable to produce an accurate and unbiased evaluation of experiences that extend over time” (2004, p. 430). When it comes to what makes one happy, people have a mixture of true beliefs (having a satisfying occupation; having a number of caring, emotionally intimate relationships; sound health; or the feeling of security from personal threat) and false beliefs (having more money [if they are middle class or above], a fast car, or a vacation home).

DISCOUNTING THE FUTURE
People tend to discount the future. If given a choice between taking ten dollars now or in ten years, it is undoubtedly more rational to take the money now. Certainly inflation will make it less valuable in ten years, and the future is uncertain. But the problem is that people tend to discount the future far too steeply. This is evident in the very low contribution rates many people make to their retirement plans. People take their money now, even when the payoff at retirement is high and the probability of an interfering event is low. In so doing, people end up making choices that are inconsistent with their life plans.

But perhaps the impulse for immediate satisfaction should be forgiven. When people lying in a magnetic resonance imaging (MRI) machine are asked to choose between two options—an item now and a more valuable one in the future—the prefrontal cortex busily calculates the various payoffs over time, lighting up the image with blood flow activity (McClure et al. 2004). But when a person chooses the present pleasure, the limbic system—which governs the emotions and spontaneous responses—also flashes brilliantly. Thus, people are biologically programmed to respond more strongly to present pleasures, and while they might find it difficult to eliminate their biases, some biases can be used to cancel out others. Richard Thaler and Shlomo Benartzi’s Save More Tomorrow Plan (SMT) is a fine example of this sort of psychological ju jitsu.

SMT uses one set of biases (the tendency toward decision-making inertia and procrastination) to counteract another bias (the failure to properly discount the future). The plan application asks prospective participants if they would like to start saving three months from now, and it commits them to doing so at the time of enrollment. The time lag allows people to experience whatever they find attractive about procrastination, but once enrolled in the plan, inertia takes over and people tend not to opt out. Thaler and Benartzi also curb a powerful psychological factor—loss aversion—that would lead people to decline to participate in the plan. People tend to weigh
losses far more heavily than gains, and so tend to work hard to avoid sure losses. Loss aversion tends to prevent people from enrolling in a program in which they will witness a decrease in their paycheck. So SMT takes the increased contribution out of the employee’s pay raise, so that it is not experienced as a loss. For those involved in this plan, saving rates more than tripled, from 3.5 percent to 11.6 percent, over 28 months.

Contemporary research into decision-making focuses on describing the processes employed by decision-makers. By discovering processes that consistently lead to decisions that are in some sense non-optimal, researchers can offer psychologically tractable proposals for improving decision-making. This research has produced, and will continue to produce, important practical and theoretical results for economics, organizational behavior, investment performance, organ donation planning, insurance, traffic theory, criminal corrections, medical diagnosis, and many other areas that are significant to people’s lives.

DECISIVE EVENTS
An event with persistent consequences that influences the economic activity in significant regions of the world, and that marks a shift in structural conditions for investment, trade, relative prices, or central state policy, is termed a decisive event. Because economic reasoning is concerned with an explanatory-factor approach to empirical regularities, decisive events often appear as abrupt and depth breaks of these regularities. For this reason, the initial occurrence that unleashes the full sequence of changes is perceived as the fundamental turning-point moment, and is often used like a marker to outline time periods and differentiate chronologies. The idea that once a turning point is reached, a cascade of irreversible consequences will follow, is akin to the representation of thermodynamic systems that are no longer in a state of equilibrium. In reality, decisive events in economic terms are equated in the short run as moments of system disequilibrium.

Within this framework, what matters is not so much the intensity, breadth, and pace of the turning-point event, but rather how the system responds to changes in the environment. In historical terms, this entails the distinction between train and explosion, between the narrative of singular occurrences and the mechanisms that generate one particular outcome: When the stock market fell almost exactly the same amount on almost exactly the
same dates in 1929 and in 1987, why did the first collapse lead to a world crisis, but the second have only limited consequences? The answer is that a stock-market crash is not enough to trigger a depression. There must be some causal mechanisms at work that contribute to spreading a single initial occurrence in a sequence of events across sectors of activity and across nations. The primary propagation channel of the 1929 crash could have been the banking panics, the postwar system of the gold standard that spread the shock by indicating that deflation policies were the appropriate remedy for the ills of the 1930s, or both. The important point to note is that decisive events join together a turning-point occurrence and a powerful propagation mechanism.

World Wars I (1914–1918) and II (1939–1945), the stock-market crash of 1929, the oil shock of 1974, and the fall of the Berlin Wall in 1989 constituted the most decisive events of the twentieth century, from an economic point of view. Each of these episodes was meaningful to historical actors before they became meaningful as objects of research. Narrative memory and intrinsic plot formation therefore established preliminary grounds and agendas in which the analysts developed their work. To most contemporary observers, the abrupt shifts were felt with some uncertainty and distress, provoked by the dense concentration of facts in short periods, and by the need for personal adjustment to a changing world. Hence, the thick time of decisive events appears cognitively and emotionally as an overload of data and occurrences that disturbs the degrees of rational belief. Under these conditions, it becomes increasingly difficult to estimate some hypotheses, given the evidence, or to forecast possible tendencies of the future.

DECLARATION OF INDEPENDENCE, U.S.

The Declaration of Independence, written in 1776, marked the birth of a new nation, the United States of America. Drafted mainly by Thomas Jefferson, edited by a committee consisting of Jefferson, John Adams, Benjamin Franklin, Roger Sherman, and Robert R. Livingston, and then by the Second Continental Congress that had appointed the committee, the Declaration set forth not only the causes that led Americans to sever their political ties with England but also a moral and political vision that speaks to the ages. In a few brief lines, penned at the beginning of America’s struggle for independence, the founders distilled their philosophy of government: individual liberty, defined by rights to life, liberty, and the pursuit of happiness, secured by a government instituted for that purpose, its powers grounded in the consent of the governed.

At the time, these were revolutionary ideas, because no people had instituted them as Americans would eventually do, first with the Constitution of 1787, then with the Bill of Rights, ratified in 1791, and finally with the amendments that followed the Civil War (1861–1865). Yet the ideas themselves grew from a history stretching back to antiquity. Two influences were seminal, however: the five-hundred-year evolution of judge-made common law in England, which fleshed out the rights individuals had against one another and, in time, against government itself; and John Locke’s Second Treatise of Government (1690), which drew upon that tradition to fashion a theory of legitimate government, grounded in natural rights. Thus, by the time Jefferson sat down to draft the Declaration, these ideas were commonplace in the colonies, even if it remained to institute them securely.

The document itself has three main parts. Invoking “the Laws of Nature and of Nature’s God,” it begins by stating the need, out of “a decent Respect to the Opinions of Mankind,” to declare the causes of the separation, then sets forth the famous lines about liberty and limited government—the moral foundation that justifies those causes. There follow next the causes themselves, the “long Train of Abuses and Usurpations” the king of England had visited upon the colonies. Finally, appealing “to the Supreme Judge of the World for the Rectitude of [their] Intentions,” the founders declare “That these United Colonies are, and of Right ought to be, Free and Independent States.”

So important are the Declaration’s famous lines setting forth the founders’ moral and political vision that they bear statement and closer examination: “WE hold these Truths to be self-evident, that all Men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty, and the Pursuit of Happiness—that to secure these Rights, Governments are instituted among Men, deriving their just Powers from the Consent of the Governed.” Note first that these truths are said to be “self-evident”—truths of reason. To be sure, the founders were men of faith, and of
various faiths; but they were mindful also that they were setting forth universal truths, truths for all people, whatever their beliefs. Thus, they appeal to reason, not to faith or mere will. Second, notice that they set forth the moral order first, then the political and legal order it entails. Following Locke, they begin the business of justification by determining first, through reason, what rights and obligations individuals have respecting one another. They can then determine how legitimate government might arise through the exercise of those rights.

Turning to the truths themselves, the founders begin with a simple premise, that all men are created equal, then define that equality as a matter of rights to life, liberty, and the pursuit of happiness. Three fundamental points emerge here. First, men are all equal only in having equal natural rights, not in any other sense. But that point is crucial because it means that no one has natural rights superior to those of anyone else; and yet it allows for the inequality that invariably arises when people exercise their liberties as they wish and may. Second, by grounding their vision in rights rather than values, virtues, or other moral notions, the founders paved the way for liberty through law. Rights define the acts that are permitted, prohibited, or required, whether or not those acts are valuable or virtuous. Finally, as a corollary, people are free to pursue happiness as they wish, by their own lights, provided only that they respect the equal rights of others in the process. Others are free to criticize these pursuits, but not to restrict them. People are free to be virtuous, however defined, but not compelled to be. That is the very essence of a free society.

To secure that freedom, however, government is the natural instrument. But one must be careful, because government itself can be tyrannical. Thus, when the founders turn at last in this passage to government, it is twice limited: by its ends—securing individual rights; and by its means—to be just, the governed must consent to its powers. Reason and consent, the two traditional sources of political legitimacy, are there joined for “a candid World” to see.

The Declaration’s principles have never been fully realized, of course. When the Constitution was drafted eleven years later it drew heavily on these principles; to ensure the union, however, it recognized slavery, albeit obliquely. The framers wrestled with the issue, hoping the institution would wither away over time. It did not. It took a civil war to end slavery, and the passage of the Civil War amendments to incorporate in the Constitution at last the grand principles of the Declaration. And in other ways too—not least, the growth of modern government—Americans have strayed from the Declaration’s vision of liberty through limited government. Nevertheless, that vision—the right of every individual to chart a course through life, free from the interference of others or of government—continues to inspire millions around the world who see in the Declaration of Independence the principles under which they themselves aspire to live.

**DECOLONIZATION**

Decolonization has shaped modern world history, and continues to do so. In the eighteenth century the American Revolution (1776–1783) laid the foundations for the United States’ regional, then world influence. In the early nineteenth century Latin and Central American territories freed themselves from Spanish and Portuguese control (e.g., Paraguay in 1811 and Brazil in 1822). The European settler populations there, and in Canada, Australia, and other areas, used European styles of organization and, if necessary, warfare, to pressure imperial powers, and the result was full independence or more limited self-government, depending on the flexibility of the imperial power. But the most dramatic wave of decolonization was concentrated in the period from 1918 to the 1960s, when more than fifty countries and more than 800 million people gained independence from European rule. More recently, since the 1990s, the breakup of the Soviet Union’s “empire” of satellite states has dramatically changed European and wider international relations, leaving the United States as the only global superpower.

As late as 1914, however, it seemed likely that most Asian and African countries would have to wait generations for internal self-government, let alone full indepen-
Decolonization

dence. Their populations were limited to traditional forms of resistance, often involving royal elites and their retainers and levies, or to localized peasant revolts against harsh rule, high taxes, and alien customs. For Asians and Africans, decolonization's roots lay with the development of new local elites trained in modern disciplines—law, medicine, civil service—and their establishment of national-level political and, later, military organizations. These organizations had a dual significance: They could bridge tribal and regional differences to provide a "nation" in whose name sovereignty could be demanded, and they could organize state-wide resistance, ranging from peaceful civil disobedience to sustained guerilla warfare.

In analyzing these trends, scholars have identified three types of cause of decolonization: metrocentric, peripheral, and international. In short, these involve causes in the imperial power, in the colonized territory, and in the wider world. Some argue that one or another cause has the greatest influence: for example, that the cold war (an international cause) made postwar European empires expensive, as communist ideology blamed western capitalism and imperialism for indigenous poverty, and communist countries encouraged and aided revolts. In truth, such world or systemic tensions are not deterministic. They do exert pressure, but ultimately imperial powers may choose to maintain their empires if they are willing to accept increased costs.

The influence of metrocentric agency becomes obvious when we examine cases of empires that persisted during the cold war. One such case is the informal empire of the Soviet Union, which dominated satellite states in eastern and central Europe. When any of these states attempted to relax adherence to Soviet military and ideological norms, as Hungary did in 1956, they quickly discovered that Soviet tanks blocked their way. When Soviet "decolonization" did gather pace in the 1980s to 1990s it was not so much a result of pressures from the periphery as from Soviet President Mikhail Gorbachev's decision that openness and reform were necessary for central economic rejuvenation. Likewise, Portugal, which by the time of the cold war had one of the smallest European empires, tolerated guerilla warfare until the fall of its dictatorship in 1975 brought to power a left-wing government averse to the cost, and authoritarianism, of empire. After 1975 Portugal more or less scuttled its empire, leaving Angola, Mozambique, Guinea-Bissau, and East Timor to their own devices. Portugal's empire thus proved more durable than Britain's and France's, most of which was gone by 1971. In short, just as metrocentric concerns—centered in a metropolis or dominating central state—sometimes drive expansion, they sometimes accelerate or delay decolonization too.

Even in the case of Portugal, however, where metrocentric changes triggered the end of an overall imperial system, peripheral pressures did exist, with rebellion having started in Angola as early as 1961. Peripheral approaches also help explain individual examples of decolonization, and details such as the timing and nature of events. The demonstration effect of success in one colony can also create a domino effect, as in the Spanish colonies in the early nineteenth century, and in Soviet satellites in the 1990s, thus helping to explain the end of entire empires. In addition, in some cases only the peripheral explanation can explain how imperial powers were forced to disgorge territories they desperately clung on to. Key examples include Indochina (Vietnam), where the determination of first France (1946–1954) and then the United States (1965–1975) was ground down by Marxist-inspired nationalist guerilla forces. Likewise, in Algeria, France reluctantly ceded independence in 1961 despite initially claiming the territory as an overseas department and integral part of the French state.

Although peripheral causes can help to explain the pressures on an imperial power, and metrocentric approaches can help explain how each empire responds, neither is adequate to explain the pulses or waves of decolonization outlined above, when several empires simultaneously decolonized. International pressures and events are also indispensable in explaining how some imperial powers crashed from glory to dissolution in the space of just a few short years.

Portugal's grip on Brazil and Spain's on its colonies, for example, were at first loosened by the Napoleonic Wars, which brought virtual autonomy to Brazil. Britain's inability to quell revolt in its American colonies was as much due to France broadening the conflict as the colonists' determination. More dramatically, defeats in war allowed enemies to quickly deconstruct the Austro-Hungarian Empire after 1918, and the Japanese Empire after 1945. Clearly, changes in the international environment, for example Woodrow Wilson's championing of "self-determination" as a fundamental principle in international affairs in 1917, and the United Nations' support for decolonization after 1945, also raised the costs and lowered the benefits of empire.

The above discussion adheres to a classic idea of decolonization as constitutional and legal liberation. This is decolonization as the formal handover of sovereignty, the lowering of the old flag and the raising of the new. Some people argue that decolonization is precisely that, others that it is much more, and does not always end at the point where formal independence starts. At one level, formal independence does not preclude metropolitan companies' controlling much of the economy, and metropolitan scheming in local politics, even up to encouraging
the removal of elected local rulers. After 1961 French culture continued to have an effect on elites in formally independent French-speaking Africa, and military and economic agreements ensured ongoing influence. This raises the question of how far decolonization goes to remove the ongoing political and economic hegemony of a former colonial power.

If decolonization is the removal of domination by nonindigenous forces, this could include the colonizer’s legacies in other areas, such as race and culture. One might think of full decolonization in terms of three Ms: the mass, the mind, and the metropole. Traditional approaches concentrate only on the mass, or the colonial territory itself and its main political, security, and financial institutions. Newer approaches also emphasize decolonizing the mind (i.e., freeing postcolonial culture and thought from tutelage to western ideas) and the metropole (i.e., freeing the metropole from its own tendency to inferiorize and dominate other peoples and territories). In this latter sense, postcolonialism (as a process of contesting the impact of colonialism after formal independence) and decolonization (as a process of removing control of indigenous peoples by other groups) overlap. The object of decolonization is not just government, but also other areas such as economics and its effect on the culture, ideas, and institutions of imperial domination.

The two approaches can be seen operating together through individuals such as Martinique’s Frantz Fanon (1925–1961), for whom imperialism was not so much a formal process as a mental hegemony, a domination of how people think. French imperialism aimed to absorb indigenous elites as francophone, and Fanon came from a family in Martinique—a French overseas department—which initially thought in these terms. But his experiences of discrimination in the Free French Forces, as a doctor in France, and of imperial violence in Algeria, where as a psychiatrist he treated victims of torture, convinced him that domination was exercised by a social system and experienced as a mental state not dissimilar to a mental illness. He later concluded that violent struggle was a powerful antidote to the condition. For him the violence was in itself empowering and liberating. He later supported the Algerian resistance, and his books Black Skin, White Masks (1952) and The Wretched of the Earth (1961)—the latter calling for peasant revolution to ensure real transfer of economic power, rather than mere accommodation— influenced other revolutionary leaders such as Che Guevara (1928–1967) and Steve Biko (1946–1977). Fanon’s own ideas, such as his conception of imperialism as an affliction affecting both the colonized and the colonizer, are important as an example of a general trend toward highlighting the cultural and aspects of decolonization and postcolonialism.

Decolonization remains a very real issue. It is an issue in terms of whether existing groups under outside domination, such as Tibet and Muslim Xinjiang under China’s hand, will one day assert nationhood, perhaps using force to demand independence. It is an issue in terms of whether the United States has inherited Britain’s mantle as an “informal empire,” asserting supposedly universal liberal and democratic values by “gunboat imperialism.” It is an issue in terms of how far “first peoples” such as Canada’s Inuit and Australia’s Aboriginals will demand, and receive, further compensation and assistance to counter past repression and past appropriation of their lands. And finally it is an issue in terms of ex-imperial powers reexamining the domestic vestiges of imperialism in their populations, their prejudices, and their cultures.

DEFENSE
Defense, in the social sciences, traditionally focuses on how states jockey for premier position in the global system. Periodically, it also examines preparations by different societies for countering internal and external threats.

Self-defense, in the dominant realist school of international relations, stands alone as the raison d’être of the
Defense

state. Other functions proposed by liberal philosophers, including providing the laws and infrastructure for commerce or protecting individual freedom of citizens, presumptively come second to survival. This does not mean, however, that the demands of defense, even for the realist, are met at any price. In fact, defense policy may be understood as the art of balancing the combined risks of destruction from war or dissolution from rebellion against the benefits of preserving cherished principles of the state.

ORIGINS OF DEFENSE

These founding principles reside in the provisions of a so-called social contract between citizens and their governing institutions. Beyond the explicit articles of written constitutions, the social contract as a concept captures the pattern of expectations concerning rights and obligations for individuals living under protection of the state. When states are under extreme circumstances, when internal or external disintegrating forces are high, Thomas Hobbes in his classic work Leviathan ([1651] 1985) argued people would and should accept sharp curtailment of their liberty to fortify the state.

As a counterweight to this prescription for centralization of power in the state, most Enlightenment liberals stressed the importance of preserving individual freedoms and maintaining ultimate accountability of the government to its people, even in the face of grave security threats. Historically, through the evolution of the international system of states during the nineteenth century, the advent of nuclear weapons in the twentieth century, and the rise of nonstate security actors in the twenty-first century, states have had to reconcile the imperatives of self-preservation with the implicit call of their social contract to provide for a better life at home.

DEFENSE POLICY PROCESS

The responsibility for striking this balance lies primarily with the executive and legislative powers of the state, though in cases where there is an independent judiciary defense decisions may be countermanded according to legal codes. In keeping with Hobbes's line of argument, the more defense measures hinge on emergency maneuvers and closely held intelligence, the more power tends to be concentrated in the executive, even in otherwise liberal societies. Defense, however, involves a mixture of long-term reflective planning and time-critical choices. In practice, there is often feedback between various stages of defense policy, but as a point of departure Peter L. Hays, Brenda J. Vallance, and Alan R. Van Tassel (1997) provide a linear guide to the process as follows.

Responsible officials assess the threat environment. Of common concern to all states are threats to territorial integrity. Assessing these challenges involves geopolitical calculations based on resource capacity and the geographical position of potential rivals. In addition, national defense must account for intentions, essentially the risk that foreign capability will actually be organized and directed against the state. For most states in the international system, high-probability threats to existence are rare. Consequently, political leaders usually have the luxury of determining many of their defense priorities not just according to the necessity for survival but also through the lens of national values. The ethnic composition of a foreign state, its respect for human rights, or the quality of its democracy may affect the level of cooperation it enjoys from external actors in its own defense.

Grand strategy is the art of matching finite national capabilities against interests so as to reduce vulnerabilities and maximize opportunities in the international environment. The means for grand strategy are conventionally categorized according to economic, military, and diplomatic instruments of power. While national security depends on all the available instruments, defense analysis normally focuses on the role of the military instrument in the development and implementation of grand strategy.

States trade off between expanding their total resources for defense through alliances and increasing their autonomy through arms buildup. During the cold war, U.S. diplomatic efforts to nurture the North Atlantic Treaty Organization (NATO) were part of a grand strategy of containment, which relied on external balancing to prevent a Soviet invasion of Western Europe. The U.S.-Soviet rivalry also featured internal balancing as both sides spent vast sums to greatly expand the number and variety of nuclear weapons under their control.

Both external and internal balancing during the cold war supported containment, largely based on deterrence, or defense through the credible threat of imposing unacceptable costs on an enemy to dissuade it from attack. Still, even in the era of the superpower nuclear standoff, defense strategists in some cases lowered the threshold for taking the military offensive. Israel famously ordered a preemptive strike on massed Egyptian air power to clear the way to victory in the Six-Day War of 1967. Both the United States and the Soviet Union employed preventive uses of force in buffer zones such as Eastern Europe and the Caribbean to cover vulnerabilities in their respective spheres of influence. With the relaxation of tensions between the largest nuclear powers and the rise of terrorist organizations demonstrating their potential to make strategic use of weapons of mass destruction, the defense pendulum swung farther from deterrence toward preemptive and preventive grand strategies.
DEFENSE CHALLENGES

In *Taming the Sovereigns: Institutional Change in International Politics* (2004), Kalevi J. Holsti marks a turning point as well in the relationship between defense policy and the normal workings of the international system. Through the nineteenth and most of the twentieth century, states—as opposed to feudal structures, tribal groups, or warlords—reigned as the supreme institutions for harnessing people and technology in defense of their interests. Especially after the Industrial Revolution and the rise of nationalism, highly capitalized technology came to dominate the equation for national capability. So much so, that during the nuclear arms race there arose the question of whether or not the most powerful states, with no recourse to international governing authority, possessed the political acumen to save themselves from arsenals that promised “mutual assured destruction.”

While the likelihood of a great power launching thousands of nuclear warheads in the name of defense declined after the end of the cold war, the September 11, 2001, terrorist attacks demonstrated in dramatic fashion a shift in the nature of the deadliest challenges confronting civilization among nations. Though military technologies for both mass destruction and precision strike continue to evolve, the greater danger may now lie with the rise of new types of organizations that defy the state monopoly on force.

Above the state, international organizations such as the United Nations confer legitimacy and broker burden-sharing agreements as modern great powers wheel about to secure globalized interests. With the value of their security functions rising, international organizations gain voice and impose new constraints on defense calculations for even the most powerful sovereigns.

Constrained states, as John Arquilla and David Ronfeldt discuss in *In Athena's Camp: Preparing for Conflict in the Information Age* (1997), also perceive growing threats from below. Ethnic paramilitaries, warlords, criminal gangs, and Al-Qaeda–inspired terrorist cells, all draw sustenance from hard-to-kill transnational networks and exploit vulnerabilities in economically developed, highly interdependent societies. In the post–September 11 environment, violent nonstate actors challenge weak or failing states for control of territory and population seemingly without need of supplies from governments bound by an ultimate interest in continuation of the interstate system. Faced with a millennial challenge not simply against particular regimes but also to the primacy of the nation-state in international governance, both developed and developing countries have adapted by delegating more of their core function—providing national defense—to intergovernmental organizations such as NATO or to substate actors such as private security companies.

DEFENSE, NATIONAL

National security would seem to be a simple concept to define. Joseph Nye Jr., who served as assistant secretary of defense for international security affairs (1994–1995) during President Bill Clinton’s first term, observed that security is like oxygen—it is essential to all other governmental activity. Without it, a government is likely to become paralyzed and incapable of action, and may ultimately risk collapse. Not surprisingly, states generally regard national security as their primary responsibility. In common American parlance, the term national security has almost become a cliché and refers to the government’s efforts to defend the state from threats, mainly military threats but perhaps internal subversion as well. In other words, “security” seemingly equates to “defense.” However, while defense is an integral aspect of security, military defense does not exhaust the range of functions that governments must perform to ensure security, nor does it reflect the institutional affiliations of the people who work to provide security.

The term national defense evokes an era when the nation and the state, especially in northwest Europe and the United States, were thought to be one and the same—hence the term nation-state. Defense of the state meant defense of the nation, and security was largely defined in ways that reinforced this equation. In fact, virtually every modern state is multinational or multiethnic, even multi-confessional. Frequently, this diversity of religion directly
relates to diversity of nationalities in the state, and many states are driven by conflicts among these diverse religions and nationalities. Therefore, a state, to be secure, must act in ways that forestall the emergence of crippling interethnic or interreligious confrontations. Such internal divisions frequently invite foreign intervention. In these contexts, security extends beyond defense against external invaders to include the prevention of civil war. Such a situation developed, for example, in Iraq, where contending Islamic groups became divided on the basis of religion and ethnicity (Shia and Sunni) and nationality (Sunni, Shia, and Kurd), and where foreigners intervened on every side.

Such internal divisions also developed in conflicts in Africa and the former Yugoslavia in the late twentieth and early twenty-first centuries. Many such conflicts, particularly in the third world, exemplify the fact that security pertains as much to the assurance of continuing internal order as it does to defense of the realm. Many third world countries simultaneously face the exigencies of state-building—that is, assuring internal security and defense against external threats—without sufficient time or resources to compete successfully with other more established states. Not surprisingly, the primary concern of the government becomes internal security and its continuation in power, leading to a proliferation of military, intelligence, and police forces. Indeed, for these states, and arguably even for transitional states like Russia during the 1990s and early 2000s, internal police forces are granted greater state resources than regular armies, this being a key indicator of the primacy of internal security as part of national security. Nevertheless, if states cannot defend themselves militarily against threats that have arisen due to a previous failure to provide security, the states themselves may fail.

Because of the breadth of domestic or foreign threats to the security of a society or a state in the modern world, national security can no longer be limited to defense against military attacks or internal unrest. Governments in the twenty-first century must defend against a multitude of threats to the health, viability, and integrity of society. Such threats extend beyond the canonical threat of war with another state or domestic unrest that culminates in revolution or civil war. The potential threats to state security include terrorism, large-scale criminality, narcotics trafficking, uncontrolled immigration, natural disasters, epidemics, and chemical and biological warfare. The threats facing states may also include major international economic crises, such as the Asian financial crisis of 1997 to 1998. These threats also tend increasingly to spill over national borders, often uniting the transnational purveyors of the threat (e.g., terrorist movements, crime syndicates). The range of potential threats blurs the distinction between military and police missions. Often, both institutions act together to promote security, as exemplified by the participation of the U.S. military in antidrug activities, homeland security, and the response to natural disasters. Thus, in the wake of hurricanes Katrina and Rita in 2005, calls multiplied in the United States for revising legal codes to permit greater scope for domestic military action during natural disasters.

Homeland security was proclaimed as the U.S. military’s main mission after the terrorist attacks of September 11, 2001, leading to a dramatic expansion of its domestic role. This change has reopened the debate over the legitimate role of the armed forces in domestic security, and has stimulated the Department of Defense, the armed services, and intelligence agencies such as the FBI and CIA to advocate substantial enhancement of their domestic powers. Thus the erosion of distinctions between security and defense, or between power projection abroad and homeland defense, creates difficult and persisting issues of possible encroachments on the domestic civil rights of Americans. These matters ultimately must be decided by the courts and legislatures. But their reemergence indicates that a fundamental component of national security remains the internal balance of power between civilian and democratic authorities and the armed forces that are supposed to be subordinate to them. These issues also raise the equally perennial question of the legal limits of state power in wartime, when it becomes too easy to argue that defense of the state overrides previously granted rights that are enjoyed without question (or seemingly so) in peacetime.

The same issues have arisen in other countries. The war that began in 1991 in the republic of Chechnya in southeastern Russia served as the primary justification for the curtailment of Russian federalism and of innumerable civil rights for the population and the media. In Great Britain, the government’s reaction to the terrorist bombings in July 2005 occasioned a lively debate over the civil rights of Muslim immigrants to Great Britain and of British citizens in general. Thus the contemporary threat environment, punctuated by the global fear of and war against terrorism, is a manifestation of global trends and issues. This overall similarity of trends and agendas relates in important ways to the universal and transnational nature of twenty-first-century threats. And because contemporary threats to security are transnational, they must often be dealt with in international forums or through multilateral cooperation. The erosion of distinctions between security and defense, along with the globalization of threats, has generated global counterresponses.

Nonetheless, if states cannot defend against any or some combination, let alone all, of these threats, their security immediately becomes at risk as societal cohesion comes under threat. Indonesia’s regime collapsed in 1998 for failing to cope with the Asian financial crisis. The gov-
ernments of China, Russia, and the countries of Central Asia also believe that their internal cohesion and thus security are under threat from the ideologies of democracy, allegedly supported by foreign nongovernmental organizations and by states who use these organizations, as well as the tools of the media and information technology, to undermine their regimes. These regimes’ leaders frequently charge that the United States is orchestrating a campaign to promote democracy, and even that democracy threatens their security and sovereignty.

Thus the term national security must encompass societal or state security against the entire range of threats described above, including traditional war, insurgency, and revolution. National security reaches beyond the defense of the state to encompass the goal of achieving and sustaining a broader societal cohesion, resilience, and integrity that can withstand numerous shocks or threats. Since the contemporary environment makes ensuring state security in this broad sense government’s most fundamental responsibility, with defense being the main component of the provision of security, the burden of state spending on security and defense is huge. Similarly, many state organizations beyond defense ministries are involved in providing security, and their missions are steadily expanding.

Strategic threats to a society or state, threats that can overwhelm a state’s ability to overcome or even effectively respond to them, have become multidimensional, and may originate from and be targeted at the land, the seas and other bodies of water, the air, space, and the ether (cyberspace). Consequently, threats, as well as the response to them, are no longer exclusively determined by geography. Any actor anywhere in the world, be it an individual or an institution, with the means to carry out an attack, can target anyone or any object in any of these dimensions. Moreover, the originator of these threats need not launch an attack from his or her point of origin. All an enemy need do is set an attack in motion, as the Saudi-born terrorist Osama bin Laden did in 2001 when he initiated attacks on New York City and the Washington, D.C., area from Afghanistan. Those actually carrying out the mission can identify the appropriate medium and locales wherein they can launch an attack. This backdrop also greatly multiplies the possibilities for shadowy relationships between sponsoring states and transnational terrorist organizations like Al-Qaeda. In America’s “war on terror,” for example, the enemy has no geographical center.

As a result, the number of possible strategic targets is greatly expanded. Any place on earth can become a target or a launching site for major attacks. Since no state can preplan sufficiently to ensure global and multidimensional readiness, governments everywhere face so variegated a repertoire of threats that they must devise new methods of responding or they must greatly transform existing institutions to meet the variety of threats. Many more issues than before now come under the rubric of national security, as do many more state organs and policies. Since providing for security has become even more of a challenge to a state’s capability and resources, often stretching the state beyond the breaking point, expanded multilateral forms of security cooperation among states have developed. This cooperation may involve agencies responsible for the military, police, intelligence, public health, the treasury, immigration, and so on. This expanded burden upon states adds substantially to the pressures upon states who face major challenges of state building (e.g., Afghanistan, and Pakistan) and helps explain why so many regimes are on the verge of failure.

The centrality of security as the state’s preeminent responsibility emerges clearly from comparisons of different states’ approaches to the task of providing security. This is not just because of the priority accorded in the United States to homeland defense since 2001. In the war on terrorism, security is no longer the sole province of the regular armed forces, whereas in the United States as well as in other nations, defense remains very much a military prerogative. Security, on the other hand, can be provided by the police forces, intelligence agencies, bank inspectors, public health services, and airport security personnel. Indeed, it is universally agreed that all providers of security, wherever they may function, ideally should be coordinated so that efforts and information flow freely between different agencies, and that effective responses to threats may be coordinated either among the various components of national bureaucracies or among transnational institutions.

In Afghanistan since 2001, for example, the North Atlantic Treaty Organization (NATO) provides defense in support of the U.S. military mission there. In fact, both NATO and the U.S. armed forces became engaged in the overall reconstruction of the state after the deposing of the Taliban government in late 2001. The situation was similar in Iraq after U.S. forces invaded the country in 2003. Such international cooperation is necessary, given the nature of the contemporary threat environment and the rise of what scholars discern as new paradigms of war. In one new paradigm, warfare takes place among the people and entails more than just providing defense. In such a war, it becomes necessary to provide security and to enable the revival of a functioning state.

This is by no means an exclusively American view. French defense minister Michèle Alliot-Marie wrote that “to respond to such testing situations, solutions must be developed which if not purely military, must be military above all” (2005, p. 15). In other words, the expanded threat environment of the twenty-first century imposes
security and defense missions on the armed forces that extend far beyond previous concepts of security and defense, or the simple notion of operational victory over opposing armed forces. This environment necessarily brings into the picture both greater transnational threats and greater cooperation against them, as well as expanded roles in the provision of security for a much broader range of state agencies.

At the same time, it is not the case that all states view the expanded range of threats in the same light. Whereas the U.S. government sees terrorism primarily in terms of a military threat, Germany (at least under the administration [1998–2005] of Chancellor Gerhard Schroeder) sees terrorism mainly as a criminal phenomenon that must be confronted by police and nonmilitary measures. Italy, on the other hand, provides for a much greater range of military involvement under the rubric of national and civil defense. However, many states and analysts of international security affairs warn that despite the enlistment of the armed forces in antiterrorist operations, antiterrorism must not supplant the traditional defense missions of the regular armed forces.

Security, therefore, is broader than defense and encompasses efforts to maintain the well-being and integrity of society as a whole. Defense, in contrast, relates to ensuring that the state itself and its citizens, armed forces, and vital interests are not attacked, or if they are attacked, that the attacker is defeated. Undoubtedly, security encompasses defense, but not vice versa. Moreover, there is no universal agreement on the nature of the threat posed by terrorists, as the German example illustrates. Neither is it possible to assume that the provision of security in this broad comprehensive sense will eclipse the need for armies to defend against major attacks on a state’s vital interests and resources, human or material. The September 11, 2001, attacks were an act of war carried out against the United States on a global scale and should be seen as such, even if the entire range of instruments of power available to the U.S. government must be brought into play across a broad agenda that encompasses such realms as financial monitoring, antiproliferation, public health, and emergency management.

National security does not refer merely to national defense, as it did during the cold war. But, at the same time, it cannot mean less than national defense. War remains the ultimate argument of states, and defense, even more than security in the broad sense, remains their primary responsibility. While it is true that failure to provide adequate security, in the comprehensive definition of the term given here, places a state’s future at risk, failure to defend the state against violent threats transforms that risk into the certainty of defeat. While security encompasses defense, defense is the most critical aspect of security and is likely to remain so.

DEFORESTATION

Deforestation can be defined as the conversion of forested areas to something that is different. Net deforestation accounts for afforestation (the establishment of forests on land that has not been recently forested), reforestation (the reestablishment of forests on land that was recently forested), and the natural expansion of forests. While the calculation of net deforestation is comparatively easy on a small scale, it is difficult on a global scale, despite modern technology such as extensive satellite surveillance. There are several reasons for this difficulty.

First, there is no universally agreed-upon definition of forest. The first Global Biodiversity Outlook (2001) defines forests as “ecosystems in which trees are the predominant life forms” but it also notes that a more precise definition is “surprisingly elusive” (p. 91). The Food and Agricultural Organization of the United Nations (FAO) has a more liberal definition, classing forests as “ecosystems dominated by trees (defined as perennial woody
plants taller than 5 meters at maturity), where the tree crown cover exceeds 10% and the area is larger than 0.5 hectares” (a half of a hectare is about 1.2 acres) (FAO 2001, p. 365). This definition thus embraces areas that some investigators think too lightly wooded to be considered a forest.

The FAO definition of forest also includes tree plantations established for the production of timber or pulpwood (used for paper) while excluding orchards. Critics point out that the inclusion of biodiversity-poor plantations in the definition of forests understates the loss of qualities that many people associate with the word “forest.” These qualities are found in woodland areas that retain a significant “natural” element and provide habitat for varied species, including trees of different species and ages. More controversially, the FAO includes in its definition forests that are “temporarily unstocked,” such as areas that have been cleared and burned. Because the duration of clearance and the certainty of restocking are unclear, inclusion of such temporarily cleared land complicates estimates of the extent and trend of current deforestation.

Other problems arise in determining the extent and trend of global deforestation. The aggregate data on which the FAO relies is supplied by its member states (as is the case with all global data used by the UN). The survey and statistical resources in many poor countries are weak, and often declining. The greatest disagreement over the extent of deforestation concerns the biodiversity-rich tropical forests. Yet such areas are disproportionately concentrated in countries where statistical resources are weak. Remote sensing methods have been increasingly used to try to compensate for these deficiencies. However, data obtained by these methods are also imperfect, for reasons such as persistent cloud cover and the problem of ground-truthing on a global basis (comparing satellite data with data observed on the ground).

THE EXTENT OF DEFORESTATION

About 8,000 years ago, forests are estimated to have covered about 15 billion acres, almost half of the earth’s land surface. Since then human populations and fire have had a significant impact on these forests. This impact is roughly proportional to the increase in human population and its environmental impact. In the near future there is a risk that these effects may be multiplied by climate change.

A review by the Millennium Ecosystem Assessment—the most authoritative assessment of the causes, composition, and consequences of global deforestation—concluded that the world’s global forest area has shrunk by over 40 percent in recent centuries. The area of global forest in 2000 is thought to include from 9.6 to 10.9 billion acres.

The pattern of current deforestation shows two trends. At higher latitudes the boreal and temperate forest areas have either stabilized or are now expanding in size (by about 7.4 million acres per annum, of which about 2.5 million acres are plantations). However, in tropical regions, forests continue to decline in both area and quality (by about 30 million acres per annum).

Compared to the decade 1980–1990, net deforestation slowed in the following decade, from minus 30 million acres to minus 20 million acres per year. According to the Global Biodiversity Outlook 2 (2006), this trend in reduction in forest clearance has continued since 2000, with a loss of about 18 million acres per year in the five years to 2005. This decrease is mostly the result of expansion in plantations (including almost 5 million acres per annum in tropical regions). Thus, despite this slowing, the rate of loss of natural (“primary”) forests in the last two decades is thought to have remained about the same. Many forests are also declining in quality. Forest fragmentation, most commonly by the incursion of roads and agricultural settlements, leaves forests vulnerable to further disturbance, including drying, fires, and the invasion of exotic species.

TROPICAL DEFORESTATION

Tropical rainforest is the most extensive forest type in the world, constituting 26 percent of global forest area. Almost 60 percent of existing tropical forests are rain forest; the remainder are mostly sparse forests in dryland areas and degraded forests. In tropical forests, biodiversity, including of trees, is very high, with often more than 100 tree species per hectare. Tropical forests (both moist and dry) harbor from 50 percent to 90 percent of the earth’s terrestrial species.

Most tropical forests are mainly in South America (1.4 billion acres), Africa (670 million acres), and Asia (490 million acres). From 1980 to 1990 about 25 million acres of tropical forest was cleared, of which about 15 million acres were of moist forests. In the following decade, total tropical forest clearance is thought to have increased to about 37 million acres per annum (about 1.2 percent of the global tropical forest total). While some of this loss is compensated for by tropical forest plantations, plantations are much lower in biodiversity.

CONTROLLING DEFORESTATION

Deforestation has largely occurred because of the expansion of agricultural land. Increasing populations and increasing demand for products that can be grown on land that is currently forested (such as palm oil, a source of biofuel) will drive ongoing tropical deforestation. Climate change may worsen this, though it may also allow the expansion of some high-latitude forests, even if warmer winters allow increased populations of insect pests.
While there is considerable discussion of sustainable forest management, this is not yet having a significant mitigative effect. Until population growth substantially abates, the loss of quantity and especially of quality of forests in the tropics is likely to continue. And, because of climate change, tropical deforestation could continue even after population peaks.

DE GAULLE, CHARLES
1890–1970

Charles de Gaulle was the leading French statesman of the twentieth century. His military career spanned both world wars and his political career, interrupted by a temporary retreat from public affairs in the 1950s, occurred during the hardships of the 1940s and then a number of serious challenges to political stability in the 1960s. As a military commander, he advocated an aggressive, tactical approach to warfare; as a politician, he was often careful in internal matters but more outspoken in international affairs.

De Gaulle was raised in a Roman Catholic family, and at an early age he showed an interest in military affairs. He entered the Military Academy of Saint-Cyr at the age of nineteen and then joined the military in 1913, commissioned as a lieutenant. He fought in World War I (1914–1918), including at the famous 1916 battle at Verdun, and he spent almost three years as a prisoner of war. After the war, he taught at his alma mater and also attended the École Supérieure de Guerre (a war college). In 1925 Marshal Philippe Pétain (1856–1951) promoted him to the staff of the Supreme Defense Council. Two years later de Gaulle began serving as a major in the occupation army for the Rhineland, an experience that illustrated the German potential for military action. Although the French prided themselves on what they saw as the impenetrable Maginot Line, in 1933 de Gaulle wrote an article arguing for a professionalized and armored French army.

When World War II (1939–1945) began, de Gaulle was commander of a tank brigade. In 1940 he was promoted to brigadier general, a position he held until his death. In the same year, he became the French undersecretary of state for defense and war, but he left the government almost immediately when Pétain became head of the government and indicated that he wanted an armistice with the Germans. De Gaulle went to England, where he began to encourage the French to continue fighting the Germans. In August 1940 he was sentenced to death by a French military court for treason. Although de Gaulle had no political base, he was deeply committed to a free France. He formed a shadow government, eventually known as the Free French Forces, although his military background was not attractive to French liberals and his condemnation of the Pétain government meant that French conservatives held little regard for him. He also had problems with the Allies, often because of his strong commitment to a free France. De Gaulle maintained contact with French resistance groups, and he broadcast radio appeals to his fellow citizens, creating increased national recognition of his leadership.

In 1943 he moved to Algiers, Algeria, where he formed the French Committee of National Liberation. He served as co-president of the committee with Henri Giraud (1879–1949), but successfully moved Giraud out of the role, signaling his political abilities. In August 1944 de Gaulle returned to Paris with the victorious Allied armed forces; he refused to meet with the envoy Pétain sent to establish peace, and de Gaulle became head of the new French government.

De Gaulle resigned, however, in 1946 because of his dissatisfaction with the power of the various political parties that formed a new Fourth French Republic. For twelve years de Gaulle argued against the republic because he saw it as too similar to the Third French Republic,
which he thought had been unable to govern effectively. He organized a loose party, the Rally of the French People, which became powerful enough to win a sizable number of seats in the French National Assembly, but he left the group in 1953. His political activity ended temporarily in 1955, when he began to work on his memoirs, but in 1958 he returned to public life.

By the end of the 1950s, France was embroiled in a military and political conflict in one of its colonies, Algeria. De Gaulle presented himself as a candidate for prime minister in 1958, and the National Assembly authorized him to change the French constitution; in December 1958 de Gaulle was elected president of France. His changes to the nation’s constitution strengthened the position of the presidency, including giving the president ruling powers during emergencies. Despite that centralization of power, de Gaulle supported the democratic principles of the government; he also made sure he was a highly visible and even personable president, spending a great deal of time giving addresses and speaking with individual citizens. De Gaulle’s ministers were often friends from World War II, and they assisted him in maintaining a strong presidency.

Algeria presented a very difficult set of problems when de Gaulle became president, a situation that deeply split French liberals and conservatives. The former argued for Algerian independence, while the latter advocated that Algeria ought to remain a colony. The Algerian insurrectionists wanted only freedom, and de Gaulle recognized that he had to free the country. French military leaders in Algeria, however, moved against de Gaulle, forming the Secret Army Organization and taking control of Algeria in 1961. This organization indicated that it was ready to actually attack France, but de Gaulle used his presidential powers to thwart them; French citizens and the French military sided with de Gaulle. Although the Secret Army Organization continued to fight de Gaulle, using bombings and assassinations, de Gaulle’s broad support resulted in his ability to establish Algeria’s independence in 1962.

Once the Algerian situation was settled, de Gaulle moved to other national issues, including reinvigorating the economy, developing France’s own atomic bomb, and instituting constitutional changes to establish independence for France’s other colonies. Nevertheless, the position that he held upon his election in 1958 was no longer as secure because he had solved the Algerian problem. He again turned to constitutional changes as a means to strengthen his position. Previously, an electoral college consisting of local politicians elected the president; in 1962 French citizens chose between de Gaulle’s resignation and a constitutional amendment that allowed direct election of the president. The referendum was a decisive victory for de Gaulle, and his party gained control of the National Assembly later that year. As a result, de Gaulle was able to further his plans to develop France into an international power, focusing on independent actions. For example, the year after his reelection as president in 1965, he withdrew France from the military branch of the North Atlantic Treaty Organization (NATO), although France remained part of the Atlantic Alliance, a political association.

In international affairs, de Gaulle sought to convince nations that neutrality was preferable to aggression, but that approach meant he was seen as opposing the United States because he wanted the United States to withdraw from Vietnam. He also encouraged stronger relations with the Soviet Union, Eastern European countries under Soviet rule, and the People’s Republic of China. De Gaulle argued that Europe had the potential to disengage from the influence of the United States. Internal strife, however, resulted in a serious weakening of de Gaulle’s position; in May 1968 university students and left-wing unionists in France nearly toppled the government, and de Gaulle had to return from an international trip to initiate a state of emergency. Although the coalition of leftist resistance quickly fragmented because the French Communist Party did not view the students as genuine radicals, de Gaulle did not emerge as a victor. French citizens opposed the rebellion and supported de Gaulle, but when in 1969 he again proposed a constitutional change, this time to reorganize the Senate, the voters rejected the proposal. De Gaulle resigned from the presidency, and Georges Pompidou (1911–1974), who had served as France’s prime minister from 1962 to 1968, became president. De Gaulle retired, planning to finish his memoirs; he died of a heart attack in 1970.

Charles de Gaulle’s stature, in France and internationally, seems to be readily apparent and yet resists interpretation. He was able to form a liberation army and government during World War II, and he brought France through the bloody war for independence in Algeria. Although he was at the center of so much military and political activity, he resisted personification of his work, asking his supporters not to use his name as a party identification; nevertheless, they were indeed known as Gaullists. His attempts to create an internationally independent France attracted a great deal of attention, but did not necessarily result in political influence.

DEGREES OF FREEDOM

There are several ways to talk about degrees of freedom, usually shortened to \( df \) in text. A one-sentence definition for a set of data is: The number of degrees of freedom of a set of data is the dimension of the smallest space in which the data lie. From this (perhaps rather puzzling) sentence, all other descriptions of \( df \) emerge after suitable connections are established.

Consider the following set of data: \( (y_1, y_2, y_3, y_4, y_5, y_6, y_7) = (26, 32, 35, 41, 43, 51, 52) \) are 7 values of the output variable of a simple process that has been set to 7 different sets of conditions, not obtained in the indicated order but rearranged for convenience. If all these responses were separately and independently generated, we would say that these numbers have (or possess, or carry) seven degrees of freedom. If plotted in a seven-dimensional space, they would define a single, unambiguous point. (If the entire experiment were repeated, another single point, elsewhere in this space, would be observed.)

Suppose we want to estimate the true mean \( \mu \) of the distribution of possible \( y \)-values using this sample of values. The mean (or average) of the data is \( \bar{y} = 40 \). The deviations from this average are of the form \( y_i - \bar{y} = -14, -8, -5, 1, 3, 11, 12 \), respectively. These seven numbers also define the coordinates of a point in the seven-dimensional space, but the point cannot lie anywhere in the space. It is constrained by the fact that these seven numbers are now deviations from the mean and so must sum to zero. Thus the point defined by deviations from this estimated mean lies in a subspace of 6 dimensions defined by \( \Sigma(y_i - \bar{y}) = 0 \) and contained within the original 7-dimensional space. We can talk about this in the following manner: We have used the original seven data values to estimate one parameter, the mean \( \mu \). This estimated mean “carries” or “has” or “uses up” or “takes up” one degree of freedom. Consequently the 7 deviations from that mean, the so-called residuals, \( y_i - \bar{y} \) for \( i = 1, 2, \ldots, 7 \), must carry the remaining 6 \( df \). Suppose now that obtaining data from our simple process above required the setting and resetting of an input variable \( x \) and that the \( x \)-data associated with the \( y \)-data above were, in the same respective order, \( (x_1, x_2, \ldots, x_7) = (8, 9, 10, 11, 12, 13, 14) \). We might wish to check if there were a linear relationship between the \( y \) and the \( x \). This could be done by fitting a straight line, namely a first order linear regression equation of the form

\[
 y_i = \beta_0 + \beta_1 x_i + \epsilon_i, \tag{1}
\]

where \( \beta_0 \) and \( \beta_1 \) are parameters (to be estimated by the method of least squares) and \( \epsilon_i, i = 1, 2, \ldots, n \) (where \( n = 7 \) for our example) represent random errors. The least squares estimates, \( b_0 \) and \( b_1 \) of \( \beta_0 \) and \( \beta_1 \), respectively, are given by \( b_0 = -8.714, b_1 = 4.429 \) so that the fitted equation (or fitted model) is

\[
 \hat{y} = -8.714 + 4.429x \tag{2}
\]

The residuals from this regression calculation, namely the \( y_i - \hat{y} \) values using predictions obtained by substituting the 7 values of \( x \) individually into (2), are, in order, \(-0.714, 0.857, -0.571, 1.000, -1.429, 2.143, -1.286 \). These residuals, like the ones above, also sum to zero. However, because of the mathematical calculations involved in the least squares process, the sum of the cross products \( \Sigma x(y_i - \bar{y}) = 8(-0.714) + 9(0.857) + \ldots + 14(-1.286) = 0 \) also. So the estimation of the 2 parameters \( \beta_0 \) and \( \beta_1 \) has now “taken up” 2 of the original 7 \( df \), leaving the 7 residuals carrying only 7 – 2 = 5 \( df \).

Suppose at this stage we wish to estimate the variance \( \sigma^2 \) of the \( y \)-distribution. The appropriate estimate would be \( \hat{\sigma}^2 = \Sigma(y_i - \hat{y})^2/(n - 2) \) using the \( \hat{y} \) values of equation (2) and where \( n \) is the original total number of \( df \). The numerical value of this estimate is \( l([(-0.714)^2 + (0.857)^2 + (-0.571)^2 + (1.000)^2 + (-1.429)^2 + (2.143)^2 + (-1.286)^2]/(7 - 2) = 10.8586/5 = 2.172 \). Notice that the divisor \( 7 - 2 = 5 \) is the appropriate residual \( df \) left over after fitting the 2-parameter straight line model. If additional parameters were added to the model, the reduction in \( df \) would have to be adjusted suitably. For more examples and details, see Norman R. Draper and Harry Smith’s Applied Regression Analysis (1998).

More generally, all sums of squares involving response values in statistical work can be written in the form \( y'My \), where \( y' = (y_1, y_2, \ldots, y_n) \) and its transpose \( y \) are, respectively, a row and a column vector of observations and where \( M \) is a specific \( n \times n \) symmetric matrix whose diagonal elements are the coefficients of \( \hat{y} \) and whose off-diagonal entries are one-half the coefficients of \( xy \) in the sum of squares. The \( df \) attached to such a sum of squares is always the rank of the matrix \( M \). This rank can best be discovered numerically by asking a computer to produce the eigenvalues of \( M \) and counting how many of these eigenvalues are nonzero.
We can carry out various statistical tests on data like the above. These tests are not discussed here. However, all such tests involve a test statistic, which is compared to a selected percentage point of an appropriate statistical distribution. When the $n$ statistical errors $\varepsilon_i$ can be assumed to be normally distributed, tests on regression parameters typically involve either a $t(\nu)$ distribution or an $F(\nu_1, \nu_2)$ distribution, where the $\nu$s represent appropriate numbers of degrees of freedom determined by the $df$ of quantities occurring in the tests. Tables of the percentage points of $t$ and $F$ distributions appear in most statistical textbooks, tabulated by their degrees of freedom.

Another area where degrees of freedom need to be calculated is contingency tables, in which discrete (noncontinuous) data arise in categories such as the number of piston-ring failures in four compressors, each of which has three sections, the North, the Center, and the South. This particular example leads to a $4 \times 3$ 2-way table with 12 entries. The test statistic in this type of problem is distributed approximately as a $\chi^2(\nu)$ variable where, for our example, $\nu = (4 - 1)(3 - 1) = 6$. Again, percentage points of $\chi^2$ distributions appear in most statistical textbooks. A lucid account of this and similar examples is in Owen L. Davies and Peter L. Goldsmith’s Statistical Methods in Research and Production (1986, pp. 317–334).

There exists, in the area of nonparametric regression, the similar concept of equivalent degrees of freedom. For this, see P. J. Green and B. W. Silverman’s Nonparametric Regression and Generalized Linear Models (1994, p. 37).

DEINDUSTRIALIZATION

SEE Neighborhood Effects.
the effort in the mid-1990s by two World Bank economists, Klaus Deininger and Lyn Squire, to put together what they described in a 1996 article as a “new data set on inequality” that would “represent a significant expansion in coverage and a substantial improvement in quality” as “compared with earlier data sets” (Deininger and Squire 1996, p. 566). They noted that “although a large number of earlier studies on inequality have amassed substantial data on inequality, the information included is often of dubious quality,” and they indicated that their own compilation was “based on household surveys, on comprehensive coverage of the population, and on comprehensive coverage of income sources” (p. 567). Deininger and Squire explained why they used two types of distributional indicators—the Gini coefficient (an aggregate measure covering the full population) and the population-quintile shares (a disaggregated index permitting comparisons of population groups)—and highlighted the advantages and limitations of the new dataset. In particular, they explained how to distinguish “high-quality data” from entries that are less reliable and emphasized the advantages of using the new dataset for time-series analysis. The full Deininger-Squire dataset was made available to other researchers and became a standard resource for social scientists.

The Deininger-Squire dataset covers 138 countries in total, though the density of the coverage varies a good deal. For some countries dozens of observations are available, whereas for other countries the number of observations is much smaller. The coverage extends from 1890 to 1996, though the bulk of the information is from the 1960s to the early 1990s, after which the coverage is spotty despite periodic updates. As a result, researchers interested in studying patterns of income distribution since the early 1990s, particularly those who want to examine how income distribution has been affected by the economic and political transformations of the former communist countries in East-Central Europe, have relied on other sources of data that in some cases are of lower quality.

After Deininger and Squire presented their initial dataset, a few other large research institutes sought to compile new panel datasets that would fill in some of the gaps and bolster the quality of the data. Most of these undertakings were designed to build on the Deininger-Squire dataset, though a few were intended to supplant the Deininger-Squire project by relying on different distributional indicators and alternative sources of information. The most successful effort to put together a new dataset—one that built on but went well beyond the Deininger-Squire project—was WIDER’s compilation of its World Income Inequality Database (WIID), which increased the coverage to 152 countries, extended the timeframe to 2003, augmented the number of distributional indicators (including decile as well as quintile shares and the use of an adjusted Gini coefficient to supplement the reported Gini numbers), and expanded the number of data observations to provide for higher quality. The first version of WIID was compiled from 1997 to 1999 and made available in September 2000, and a second, substantially improved version was released in June 2005. WIDER has continued to update the WIID since 2005, allowing further improvements in the quality of data, the extent of international coverage, and the length of the time series.

Despite these advances, the Deininger-Squire project will remain important as the first systematic attempt to compile high-quality data for comparisons of income distribution in dozens of countries over several decades. The Deininger-Squire effort provided a crucial foundation for subsequent compilations of high-quality data on income distribution.

DEMAND

In economics, demand theory examines the purchasing behavior of an individual, or of a group of individuals, in terms of its responses to changes in purchasing constraints
or other institutional factors. In the most basic setting, an individual chooses a bundle of commodities, considering both their prices and a maximum income that he or she can spend. It is assumed that the individual compares bundles of commodities according to his or her own preferences, and that he or she chooses to purchase the best bundle that is affordable; in economics, this type of behavior is called “rational” or “preference maximizing.”

The first systematic analysis of this problem was done by Leon Walras in 1874. In 1886 Giovanni Antonelli studied the problem of constructing preferences that can explain a given demand function, and in 1915 Eugene Slutsky obtained a full set of implications of preference maximization on demand behavior. In the mid-twentieth century, the economist Paul Samuelson called for a revision of the theory, whereby observable behavior, rather than unobservable preferences, would constitute the foundation of demand theory. This proposal led to the development of revealed-preference analysis, an exhaustive series of conditions that must be satisfied by demand behavior, if it is consistent with preference maximization.

The standard problem of demand theory is that of an individual who chooses a bundle of $L$ commodities, ranking different bundles according to his or her preferences. The individual faces prices $p = (p_1, \ldots, p_L)$ and can spend up to a nominal income of $m$. Consumption bundles are denoted by $x = (x_1, \ldots, x_L)$. A rational individual chooses a bundle $\hat{x}$ that is:

1. feasible: $p \cdot \hat{x} = p_1\hat{x}_1 + \ldots + p_L\hat{x}_L \leq m$; and
2. optimal: there does not exist an alternative bundle that the consumer can afford and prefers to $\hat{x}$.

Under well-known assumptions on the preferences of the individual, one such $\hat{x}$ is guaranteed to exist, and is uniquely defined. Then, $x(p, m) = \hat{x}$ is known as the Marshallian demand of the individual, and constitutes the central element of demand theory: It says how much of each commodity the consumer demands, as a function of the prices he or she encounters in the market and of the income he or she has.

Function $x$ is homogeneous of degree zero: multiplying all prices and income by the same positive number does not change demand. When a consumer prefers more to less consumption of at least one commodity, Marshallian demand satisfies Walras’s law: the consumer will spend all his or her income, so $p \cdot x(p, m) = m$. When Marshallian demand is differentiable, these properties impose restrictions on the derivatives of the demand with respect to prices and income, which can be used to restrict empirical estimations of demand. More importantly, the substitution matrix, $S$, defined by $S(p, m) = D_p x(p, m) + D_m x(p, m)x(p, m)^e$, and which isolates the effects of changes in relative prices, is a symmetric, negative-semidefinite matrix of rank $L - 1$. Suppose that the preferences of the consumer are represented by a utility function $u$. Then, the indirect utility function, $v$, defined by $v(p, m) = u(x(p, m))$, and which measures the utility that the consumer obtains when he or she faces income $m$ and prices $p$, is homogeneous of degree zero and, remarkably, satisfies Roy’s identity: the negative of the ratio of the derivative of the indirect utility with respect to the price of a commodity to the marginal utility of income equals the Marshallian demand for that commodity; formally, $-\left(\frac{\partial v}{\partial p}(p, m)\right) - D_p v(p, m) = x(p, m)^e$.

Representability of preferences—via utility functions that assigned higher utility levels to more preferred bundles than to less preferred bundles—allows for an auxiliary problem: fixing a benchmark utility level $\bar{u}$, and given prices $p$, determine a bundle $\hat{x}$ such that:

1. gives at least that level of utility: $u(\hat{x}) \geq \bar{u}$; and
2. minimizes expenditure: every other bundle that gives utility of at least $\bar{u}$ costs at least $p \cdot \hat{x}$.

The solution to this problem defines the Hicksian demand function, $h(p, \bar{u}) = \hat{x}$, whose cost defines the expenditure function, $e(p, \bar{u}) = p \cdot h(p, \bar{u})$. Functions $h(p, \bar{u})$ and $e(p, \bar{u})$ are, respectively, homogeneous of degrees zero and one in prices. When small changes of consumption only induce small changes of utility (a condition known as “continuity of preferences”), the utility level given by the expenditure-minimizing bundle is exactly the required level: $u(h(p, \bar{u})) = \bar{u}$. Function $e$ is strictly increasing in $\bar{u}$ and nondecreasing and concave in $p$, while Hicksian demand satisfies the “compensated law of demand” (this is not true for Marshallian demand), in a sense that Hicksian demands are nonincreasing in prices: $(p - p^e) \cdot (h(p, \bar{u}) - h(p', \bar{u}))$. Under differentiability, Hicksian demand satisfies Shephard’s lemma: the derivative of the expenditure function with respect to the price of a commodity equals the Hicksian demand for that commodity, $D_p e(p, \bar{u}) = h(p, \bar{u})$.

Duality theory establishes, with minor qualifications, that Marshallian and Hicksian demands mirror each other: (1) the solution of the expenditure minimization problem also solves the preference maximization problem at income equal to the minimized expenditure: $x(p, e(p, \bar{u})) = h(p, \bar{u})$; (2) the solution of the utility maximization problem also solves the expenditure minimization problem at benchmark utility equal to the maximized utility: $h(p, v(p, m)) = x(p, m)$; (3) the maximal utility achievable with income equal to the minimized expenditure is the benchmark utility, $v(p, e(p, \bar{u})) = \bar{u}$; and (4) with lower income, it is impossible to obtain at least the maximized utility level, $e(p, v(p, m)) = m$. Shephard’s lemma shows that the first equality yields the Slutsky decomposition: $D_p e(p, \bar{u}) = S(p, e(p, \bar{u}))$, which allows for empirical esti-
mations of Hicksian demand. A commodity is said to be inferior if its demand decreases when the consumer has more income, and “Giffen” if it increases when the price of the commodity increases. It follows from Slutsky decomposition and the compensated law of demand (for Hicksian demands) that Giffen commodities are inferior.

Samuelson’s program looked for conditions on demand data that were equivalent to the existence of the unobservable preferences: Given a series (p, m, x) of observations of prices, incomes, and demanded bundles, do there exist preferences such that, at every observation, the observed demand is rational according to those preferences? A necessary condition for the existence of such preferences is the Weak Axiom of Revealed Preference, or WARP: If p · x ≤ m and x ≠ x, then p · x > m; that is, if the bundle purchased at observation t, x, could have been purchased at t (since it was affordable) but bundle x was purchased instead, then it must be that the consumer prefers bundle x to bundle x. Then, at observation t, when the consumer actually purchased bundle x, x, it must be that the more preferred bundle, x, was not affordable. WARP is not, however, a sufficient condition. It compares only pairs of bundles, whereas rationality requires comparisons of sequences of bundles, since it implies that preference is a transitive relation. A transitive chain of reasonings—like the ones posed by WARP, known as the Strong Axiom of Revealed Preference—is a necessary and sufficient condition for rationality.

Antonelli’s “integrability” result shows that homogeneity of degree zero, symmetry and negative semi-definiteness of the substitution matrix, and Walras’s law exhaust the necessary conditions of a rational demand. Using the solution to the system of differential equations implied by S, one can construct an expenditure function whose variation with respect to prices can be used to preferences that, when maximized, would yield the observed demand behavior.

The separability problem, first considered by John Hicks, studies how a group of commodities whose prices are kept in fixed proportions can be treated as a single, composite commodity whose price is constructed through the aggregation of the individual prices. This analysis provides the basis for the construction of price indices. A related problem assumes that preferences satisfy the following separability property: a group of commodities exists whose variation is ranked by the individual independently of the level of consumption of all other commodities. In this case, there is a “subutility” function, defined for the group in question, and the overall utility depends on the consumption of the group only via the subutility level. When preferences satisfy this separability condition, demand can be determined in a two-stage process: first, the individual decides how much to spend in the group, and then the individual decides how to allocate expenditures across commodities in the group.

Suppose that there is a set of consumers {1, ..., i, ..., I}, with individual variables indexed by i. The aggregate demand function is x(p, m, ... m) = x(p, m) + ... + x(p, m). The aggregation (or representative consumer) problem asks whether one can find an individual demand function x such that x(p, m, ... m) = x(p, m) + ... + x(p, m). The answer to this question is, in general, no, for it requires that all individuals have parallel wealth-expansion paths (the trajectories defined by changing individual incomes at given prices). Also, even under aggregation, individual satisfaction of WARP does not imply its satisfaction in the aggregate. WARP, in the aggregate, is obtained whenever individual Marshallian demands satisfy the law of demand, a condition that does not generally occur. (The definition of aggregate demand given here should not be confused with Hicks’s aggregate demand, which is used in macroeconomic models and in national accounts.)

In the standard setting, commodities can be interpreted to accommodate intertemporal problems. If there is only one commodity in each time period, relative prices represent interest rates, and an impatient consumer will anticipate consumption unless interest rates compensate for his or her impatience. In general, if intertemporal preferences are convex, an individual prefers a consumption plan that smooths consumption, in the sense that it avoids high levels of consumption in some periods and low levels in other periods. A canonical case for consumption smoothing is the life-cycle model originally proposed by Franco Modigliani, who divided life into three periods: (1) youth, when income is low; (2) adulthood, when income is high; and (3) retirement, when income is once again low. A consumer without restrictions will choose a smooth consumption plan that includes accruing debt during youth, repaying this debt and saving during adulthood, and spending savings during retirement. Consumption is determined by lifetime (discounted) income, while temporary deviations from this “permanent” income are accommodated by savings. A more general version of this model, involving different individuals at different stages in life, is known as the overlapping generations model. This model constitutes the basic tool for the economics of Social Security.

When the interpretation of commodities includes different states of nature, the model permits the study of uncertainty. In this case, convexity of preferences means that the individual dislikes risk and will avoid large consumption in some states if it implies low consumption in other states, unless prices compensate for this effect. This effect means that, if available, the individual will use
insurance opportunities, or, alternatively, that groups of individuals will prefer risk-sharing schemes that disseminate risks.

Applied work usually imposes particular functional forms useful for estimation. An important, flexible functional form is the Almost Ideal Demand System (AIDS), which imposes an expenditure function of the form \( e(p, u) = \alpha(p) + \beta(p)u \), where \( \alpha(p) = a_0 + \sum_l \alpha_l \log(p_l) + \sum_l \alpha_{ll} \log(p_l) \log(p_l) \) \( \beta(p) = \beta_0 \Pi p \beta_p \)

and some conditions on the parameters of these two functions are imposed. Applied work also uses “hedonic” models to impose additional structure on demand systems. It is assumed that individuals do not directly care about the commodities, but only about their attributes (physical features), which are, normally, objectively observable.

DEMENTIA

Although there is growing understanding of dementia, it remains a poorly understood condition that continues to be associated with negative attitudes and stigmas. *Dementia* is not a disease but a clinical syndrome, meaning a set of symptoms relating to the breakdown of intellectual (cognitive) functions. Operational diagnostic criteria for dementia stipulate (1) an impairment in memory; (2) an impairment in at least one other cognitive domain (e.g., language, visuospatial, knowledge and understanding, executive functions, control over social and emotional behaviors); (3) that the impairment represents a decline from the person’s previous levels of ability; and (4) that the impairments are severe enough to interfere with the person’s everyday life.

The main risk factor for the development of dementia is age. Prevalence rises from 1 in 1,000 for those aged 45 to 65; to 1 in 5 for those aged 80 to 90; to 1 in 3 among those over age 90. Until the late twentieth century, dementia in an elderly person (defined to be someone over 65 years of age) was commonly diagnosed as “senility” or “senile dementia.” These terms, however, are no longer recommended because they have been used with a lack of diagnostic rigor and there is a lack of scientific evidence to justify the diagnostic distinction between “presenile dementia” (dementia in someone under age 65) and “senile dementia” (identical symptoms in someone age 65 or more). Furthermore, the term senility carries negative connotations and implies that the dementia syndrome is an inevitability of old age. This implication is not supported by the evidence and leads to poor recognition of dementia syndrome. The symptoms of dementia in elderly people often get dismissed on the basis that these are just signs of old age, although dementia in middle-aged people is commonly misdiagnosed as a functional psychiatric disorder.

Most causes of dementia are slowly progressing neurodegenerative diseases with Alzheimer’s disease being the most common cause, accounting for 50 to 60 percent of all cases. Dementia is typically thought of as progressing from a mild stage, characterized by slips of the memory and confusion in complex situations, through a moderate stage, during which the degree of cognitive impairment intensifies to affect an increasing number of activities of daily living (e.g., use of language, ability to recognize friends and relatives, ability to make sense of the visual world, ability to use household objects or appliances effectively and safely, ability to dress and attend to personal hygiene). The severe stage of dementia is characterized by serious disability in which the person is likely to have limited language and understanding and to be totally dependent upon others for all their physical needs (eating, drinking, toileting).

However, typical schemes of dementia symptoms and progression need to be treated with extreme caution. The precise symptoms a person experiences will depend upon the particular cause of that person’s dementia and the parts of the brain that were damaged. Also, the symptoms of dementia must be understood as complex interplay between neurological damage and psychological and social variables, such as the person’s life history, personality, and quality of the care environment. These considerations are particularly important when assessing the non-cognitive symptoms of dementia, such as apathy, anxiety, wandering, or aggression. Such behaviors may reflect the individual’s personality or coping style, or they...
may be a valid response to an environment in which the person's needs and personhood are being overlooked or neglected.

With over two hundred possible causes of dementia there is still a lot to be learned about how specific causes manifest. The stages of dementia outlined are strongly influenced by the specific characteristics of Alzheimer's disease. Other forms of dementia are known to have different characteristics and growing knowledge of these differences is stimulating a move away from the generic criteria for dementia toward operational criteria for specific diagnoses (e.g., dementia of the Alzheimer type, vascular dementia). In particular, early memory loss is often cited as the key feature of dementia but this symptom has a specific link with Alzheimer's disease and there are forms of dementia in which memory loss is not a central feature (e.g., frontotemporal and Lewy body dementia).

After Alzheimer's disease, vascular dementia is the next most common form of primary dementia, accounting for 20 percent of all dementias. The blood supply to the brain can become fragile in old age and the term vascular dementia covers all forms of dementia that result from cerebrovascular pathologies. Lewy body disease, frontotemporal atrophy, alcohol abuse, and the AIDS complex are also significant causes of dementia. Some dementias are due to reversible causes (e.g., depression, hypothyroidism, vitamin B deficiency) and are called "secondary dementias." It is important that the diagnostic procedure fully investigates secondary causes for dementia before diagnosing a primary (irreversible) cause.

Pharmacological treatments for primary dementias are limited. A number of anti-cholinesterases are available that aim to alleviate some of the cognitive and functional symptoms of dementia by boosting levels of the neurotransmitter acetylcholine. These drugs were designed to specifically target the Alzheimer's disease process, although there is evidence that they may be beneficial in other forms of dementia, particularly vascular dementia and Lewy body dementia. Memantine is an alternative drug that aims to protect undamaged nerve cells from the toxic effects of high levels of the neurotransmitter glutamate, which is released in excessive amounts when cells are damaged. Both types of drug are aimed at damage limitation; neither can stop the underlying disease processes themselves. The evidence suggests anti-cholinesterases and memantine provide some benefit, but it is modest.

It is also important to support drug interventions with non-pharmacological interventions (e.g., reminiscence therapies, sensory therapies, support and discussion groups). These interventions will also not cure the problem but will protect well-being and ensure that the symptoms of dementia are not exacerbated through poor care, inappropriate expectations, and lack of support. The person with dementia's well-being is critically dependent upon that of their care giver. When care givers are not properly supported there is a high risk that their own mental and physical health will be affected, leading to a poor outcome for both the care giver and patient.

In terms of prevention, control of vascular risk, particularly cholesterol levels and hypertension, is emerging as the main preventative strategy for both vascular dementia and Alzheimer's disease. People can control their vascular risk either through diet or pharmaceuticals. An increased risk for dementia has also been associated with low education or intelligence, socioeconomic disadvantage, stress, and dietary factors (particularly the B vitamins) but untangling the direction of causation among this complex set of factors remains a significant challenge. For example, the well-established correlation between low intelligence and risk for dementia has been interpreted in terms of compensation, such that the effects of pathology are masked by higher ability, but some recent prospective studies, most notably the nun studies organized by David Snowden, suggest that low intelligence in early life may be directly involved in the pathogenesis of Alzheimer's disease. Similarly, low intake of vitamin B12 and folate are associated with elevated levels of homocysteine, another vascular risk factor which has been associated with risk for Alzheimer's disease. However, it is less clear whether increasing the dietary intake of vitamin B12 and folate has any protective effect.

DEMOCRACY

Democracy is a concept that means different things to different people. For some it is a political system that ensures political equality and self-rule. To others, it is a system that allows the presence of equal opportunities and rights. The two different conceptualizations of democracy are
based on the experiences of the two major democratic experiments that the world has seen so far: democracies in classical Greece and modern nation-states. The classical model of democracy draws its inspiration from the democratic experiments of ancient Greek city-states. In such an arrangement, citizens were both the rulers and the ruled; political sovereignty and power rested with the people. Each individual citizen had a right and an obligation to serve in administrative duties. Citizens were politically active. Women, slaves, and immigrants were, however, excluded from political participation. The small size of the cities allowed citizens to meet face to face and make direct deliberations and decisions on various issues.

There are at least two problems with the classical democratic arrangement: first, it is applicable more to small city-states than to modern nation-states. Face-to-face political participation and deliberations are easier to conduct in small communities. Modern democracies are established in much larger nation-states, making a representative form of government a necessity. Second, the conditions under which political equality is possible are not spelled out; it is simply asserted as a self-evident truth. There is no strong consensus among citizens and scholars in such an assertion. Indeed, some argue that individual liberty, which is promoted in modern democracies, makes some form of inequality inevitable.

Although there is no consensus, many scholars would agree that democracy in modern nation-states means the presence of political rights and civil liberties. Political rights include the right to vote, the right to run for office, and the presence of fair and free electoral competition; civil liberties include the presence of due process, freedom of speech and assembly, and equality before the law. Democracy, however, even as a procedural concept, is much more than the mere occurrence of elections and liberties. For instance, the presence of a majoritarian decision-making or voting mechanism, often overlooked and taken for granted, is an essential procedure in the democratic process. Elected and, in some cases, appointed representatives and officials utilize the simple majority rule as a minimum requirement for the passage of laws, judicial decisions, and administrative policies; a majority voting system is commonly used to resolve major issues, including difficult and divisive ones, by legislation or judicial interpretation. Thus, democracy may be defined as the presence of fair and free elections, civil liberties, and a majoritarian decision-making procedure. Nevertheless, not all scholars would agree with such a procedural definition. For instance, it does not fully account for the variation in the distribution of political power or influence among citizens. In other words, why is it that some citizens can exert more influence on political leaders than do others? Why do some individuals have a better chance of becoming a president or a member of parliament than others do?

TRANSITION TO DEMOCRACY

Compared to other older forms of political systems, such as autocracy, modern democracy is a relatively new phenomenon. James Bryce (1921) noted that in the early nineteenth century only Switzerland had a working democracy in Europe. Great Britain had greater freedom than any other nation on the European continent, but its government was still oligarchic. By 1921, however, Bryce observed that almost all the monarchies of Europe had become democracies. He counted twenty new democratic countries in the Western Hemisphere, and five more among the British colonies. The political evolution toward a free society heralded “the universal acceptance of democracy as the normal and natural form of government” (p. 4). Outside Europe, the United States, which is considered as the oldest democracy, had ratified its constitution in 1789. Thus, it is fair to assume that modern democracy is perhaps a consequence of the modern period, mainly of the Industrial Revolution and the Enlightenment.

The initial quality of democracy in countries such as Great Britain, Sweden, and the United States was, however, low by today’s standards. More often than not, those who had property voted. Mass democracy was possible only after the spread of mass literacy and the spread of wealth to a significant number of individuals. In other words, the conditions under which democracy has arisen would, among other things, seem to be an increased level of education and economic development. Seymour M. Lipset (1959), following Aristotle, argues that socioeconomic development leads to educated citizenry and a large middle class. An educated citizenry and a large middle class seem to be the social foundations of modern democracy. Despite the presence of counterfindings, empirical studies support Lipset’s argument. Socioeconomic development, however, may not be the only factor that accounts for the presence of democracy. The political process, particularly political leadership, and external factors are two other possible variables.

In the latter part of the eighteenth century the United States was not, for instance, a developed country. In the absence of a developed economy the framers of the U.S. Constitution were able to establish a political system that would become one of the most stable democracies in the world. To be sure, the architects of the U.S. Constitution, such as James Madison, were themselves influenced by the evolution of European political thought and by the level of education they had received. Still, not all leaders in all countries attempted to establish a freer system of governance at the time. This was a choice made by the framers. Thus, it is fair to contend that the framers of the U.S. Constitution have contributed to the emergence and development of democracy in the United States.
Democracy has, however, its variants, the most important ones being liberal democracy and social democracy. Although these variants adhere to the fundamental principles of democracy, including the presence of fair and free elections and civil liberties, they seem to have distinct socioeconomic principles. While liberal democracy stresses the importance of individuals as the deciding force of their own economic opportunities, social democracy seems to emphasize the role of the public in promoting social equity. More specifically, liberal democracy is grounded on the principle that individuals must, with little or no societal and government encroachments, be free to possess personal property and pursue their own economic interests. While such a system may bring affluence to most of the people, some individuals will probably become less successful or remain poor. By contrast, social democracy assumes that the market economic system cannot by itself evenly promote the economic interests of every individual; hence, society and government are expected to contribute to the socioeconomic well-being and advancement of the poor. The United States and Sweden may be considered as examples of the former and the latter, respectively. Such differences in economic policy cannot be exaggerated, however. In practice, even liberal democracies attempt to support the poorer segment of society and the variation in the level of such a support between the two variants seems to be only a matter of degree. Indeed, global economic competition and electoral politics seem to have tempered the different approach that the two variants of democracy have followed. Relatively higher taxation policies, as seen in social democracies, will quite likely hamper the competitiveness of corporations. Similarly, liberal democracies may have to increase their support to the poor because not doing so will probably not be favored by most people. A convergence of the two variants is apt to be inevitable.

DEMOCRATIC DEVELOPMENT
AFTER TRANSITION
Once countries transition to democratic rule, the next logical step is to stabilize such a system. Again, the stability of the new democracies seems to rest, among other things, on continuous socioeconomic development. The case of African countries right after independence suggests that poor or “immature” democracies are likely to be unstable and will probably revert to authoritarian systems. Nevertheless, the cases of India and Botswana suggest that poor democracies can become stable if they have good leadership and promote socioeconomic development. While continuous socioeconomic development may promote social mobility and affluence, good leadership tends to serve as an arbitrator for the presence of fair distribution of societal interests. By far, the most important role of democratic governments for promoting democracy has been public expenditures and investments in education, particularly in the education of impoverished children. Thus, the political process, including good political leadership and interest group politics, and continuous economic development continue to be two of the most important factors for the consolidation of democracy. But is the democratic process static or dynamic?

One can consider the cases of Sweden and Mali, for instance. While the former has been democratic since the early twentieth century, the latter has been so only since the 1990s. Can one logically assume that these two countries have an equal level of democracy? According to major democracy indices such as the Freedom House and Polity IV, the answer is, more or less, yes. Still, older democracies, particularly those in industrial countries, tend to have a higher quality of democracy than younger ones. While the basic attributes of democracy, such as fair and free electoral competition, civil liberties, and a majoritarian decision-making procedure, may be more or less present in both cases, the distribution of power among citizens...
in the two societies is quite different. Citizens in the older industrial democracies are more affluent and highly educated; as a result, they may have a greater chance of running for and winning elections for public offices and influencing public policies. Income and education resources would lead to political influence. If the income among citizens is unequal, how can they be politically equal? And because higher levels of affluence and educational achievement are a function of time, it follows that the diffusion of power or a higher level of democracy is likely to be dynamic.

Thus, the effect of socioeconomic development (and good leadership) after the transition to democracy may not merely be to maintain democracy but also to keep it evolving. Nevertheless, some scholars consider political systems as autonomous and static; that is, political systems are either autocracies or democracies. Others contend that political systems may be defined as trichotomous. These latter scholars can see at least a classification of political systems as autocracies, semi- or transitional democracies, and established democracies. A third group of scholars posit that democracy is a continuous concept. When scholars argue that democracy is continuous, they usually and mainly refer to the political process that occurs between autocratic rule and democratic transition. Dahl (1971) suggests that democratic development could go beyond the autocracy-democratic transition continuum and argues that current democracies or polyarchies are only an approximation of the ideal democracy. The main reason that no perfect democracy exists, according to Dahl, is the presence of income inequality. Thus, to speed up the establishment of a more equal democratic system, Dahl (1985) prescribes for the replacement of the current private enterprise economy by a system that allows employee-ownership of firms. He seems to imply that some form of political agreement and action would bring about political equality. Dahl’s position, however, seems to clash with individuals’ right to own private property. Indeed, the failures of ancient Greek democracies and twentieth-century communism can be partly explained by the absence of, or impediment to, economic liberty in these systems. The two forms of political systems maintained that “true democracy” could be achieved by forceful redistribution of property. What followed in these systems was political instability and economic inefficiency, leading to the demise of both political experiments. If democracy ensures economic and political freedoms and if such a process is also dynamic, it follows that the concept of democracy has to be defined accordingly.

Gizachew Tiruneh (2004) posits that the distribution of power among individuals must be considered when one rates or defines democracies. He contends that the procedural attributes of democracy, such as electoral competition, civil liberties, and a majoritarian decision-making procedure, are fundamental but once achieved they cannot be adequately used to differentiate the level of democracy among democracies. Power differences, according to Tiruneh, stem from differences in the level of income and rationality among individuals. And because individual achievement and competition are protected rights in democracies, some individuals are likely to become more successful than others. The more income an individual has, the more influence or political power he or she will possess. Assuming that the distribution of income itself is dynamic (being propelled by socioeconomic development), the diffusion of power or the level of democracy will quite likely increase over time. However, because not all individuals will have the same level of income and rationality, perfect political equality may not necessarily be achieved.

Thus, perfect political equality may, similar to the perfect competition argument in economics, be considered as a political ideal on which modern democracies may be judged. Rather than considering democracy as two separate phenomena, a political ideal and a political system, one may consider it as a single, open-ended (perhaps an infinite) process. A more achievable and optimal level of democracy, according to Tiruneh, occurs when the distribution of power, including income and rationality, among citizens takes the shape of a normal or bell curve. Modern industrial democracies have, in contrast, a skewed distribution of power (and income and rationality), where the mean or average citizen lies to the right of center. In other words, the distribution of power, income, and rationality in modern democracies are skewed toward the upper classes. As the level of democracy increases over time, however, the mean citizen would gravitate to the center of the normal curve (where the preponderant majority or the middle class is located), and it would have the most decisive voice and power in democratic politics. Whereas those individuals to the right of the mean will in theory have more power than those to the left of the mean, and it is likely that most leaders may come out of the former group, the political agendas and policies of leaders will probably be dictated by the preferences of the mean citizen. The normal or bell-curve distribution of power would represent a democratic system the quality or degree of which is apt to be optimal. In sum, Tiruneh defines democracy as “a political procedure that allows the presence of political rights, civil liberties, and a majoritarian decision-making or voting mechanism, and which permits the continuous achievement of a more equal distribution of political power” (2004, p. 473). He terms such a state of political evolution as normal democracy.

However, some scholars disagree with some aspects of Tiruneh’s theory of democracy. For instance, they may contend that democracies, after transition, will remain stabilized; that is, democracies after transition will not continuously evolve. Others may, on philosophical or moral
grounds, contend that, regardless of levels of income and rationality, citizens ought to possess an equal distribution of power. It is not clear, however, whether such possible contentions will successfully undermine Tiruneh’s thesis. What is clear is that until most or all scholars agree on a more acceptable definition of democracy, an understanding of the concept will remain incomplete.

DEMOCRACY, CHRISTIAN

Christian Democracy can be described as a political ideology that has largely been shaped by the social teaching of the Roman Catholic Church, which has given rise to political parties representing the middle of the political spectrum, between liberalism and socialism. Although many Christian Democratic political parties became less associated with the Catholic Church over time, such parties have had the greatest electoral success in European and Latin American countries that have significant Catholic populations, such as Austria, Belgium, the Netherlands, Italy, Germany, Chile, Costa Rica, El Salvador, and Venezuela. While Christian Democratic ideology and political parties had a significant impact on state and society during the second half of the twentieth century, the end of the cold war and the demise of left-oriented social movements and political parties significantly weakened Christian Democratic parties by the end of the twentieth century. The rise of the Left during the first decade of the twenty-first century in certain Latin American countries raises interesting questions about the possibility of a rebirth of Christian Democracy and a reinvigoration of Christian Democratic parties.

As a political ideology, Christian Democracy originated in response to the rise of liberalism in Europe and Latin America during the nineteenth century. It was subsequently shaped by the spread of socialism in these regions during the twentieth century. Although there is evidence that many Europeans and Latin Americans sympathized with liberals, who argued for an end to monarchies and to the privileges enjoyed by the church vis-à-vis the state, it also became clear that, unlike the radical liberals, most Europeans and Latin Americans believed that religious faith and values deserved a privileged place in society. In European countries such as Austria, Belgium, Italy, Germany, and Prussia, liberals suffered stunning electoral defeats during the late nineteenth century, largely thanks to the mobilizing power of religion.

After it became clear that religion was capable of mobilizing voters, what came to be called or categorized as Christian Democratic political parties were founded by laypersons and some clergy. Contrary to what one might assume, Catholic bishops and the Catholic Church’s hierarchy tried to prevent the formation of these political parties. During the middle of the nineteenth century, Catholic bishops feared that the formation of Catholic political parties would imply that the Catholic Church endorsed democratic political systems that might not give rise to governments respectful of what the bishops considered to be the rightful place of the church in society. By the late nineteenth century and early twentieth century, the Catholic hierarchy refused to fully endorse what came to be called Christian Democratic parties, fearing that if these parties lost elections the church would forfeit the few privileges it might otherwise manage to maintain under democratic systems.
Although they officially kept their distance from Christian Democratic parties, church leaders came to recognize the value of, and to provide ideological guidance to, organized Catholic political activity. In 1891, Pope Leo XIII issued an encyclical letter titled \textit{Rerum Novarum}, which criticized liberalism and socialism. It reaffirmed the right to private property (subject to the good of society), promoted a living wage, defended the rights of workers to organize in order to achieve a living wage, and encouraged the formation of civil society. Essentially, \textit{Rerum Novarum} reflected and reinforced the principles already promoted by Catholic political parties in Belgium, the Netherlands, Germany, and Austria. After \textit{Rerum Novarum}, Pope Pius XI’s encyclical \textit{Quadregesimo Anno} (1931) had the greatest impact on the development of Christian Democratic ideology. \textit{Quadregesimo Anno} reaffirmed the teachings of \textit{Rerum Novarum}, but it placed an even greater emphasis on the importance of subsidiarity and the rightful role of civil society. According to the principle of subsidiarity, decisions should be made, to the extent possible, by the people whose lives would be affected by the decisions. Thus, while rejecting unfettered free-market systems, it rejected the idea of an all-powerful state and centralized economic planning. \textit{Quadregesimo Anno} promoted a corporatist framework, according to which there would be institutionalized collaboration between labor and capital within the state in order to prevent class conflict and promote the common good.

The official recognition and guidance offered by Leo XIII and Pius XI spawned further development of the Christian Democratic ideological orientation by Catholic intellectuals. Foremost among them was the French philosopher Jacques Maritain, who, in his book \textit{Integral Humanism} (1936), argued that a society in which there is political democracy, social pluralism, and religious freedom is the most Christian society.

While Christian Democratic parties have varied greatly in terms of ideological emphasis, they had a significant impact in several European and some Latin American countries during the second half of the twentieth century, particularly Italy, Germany, and Chile. However, most of these parties had become very weak by the close of the twentieth century. In large part, the decline of Christian Democratic political parties may be the result of the end of the cold war and the demise of the radical Left. Christian Democrats have typically attracted people who were wary of polar ideological extremes. With the demise of radical socialism at the end of the twentieth century, Christian Democrats found themselves searching for new ideological positions and new ways to distinguish themselves from political conservatives and social liberals.

The rise of left-oriented and centralizing political leaders during the first decade of the twenty-first century in certain Latin American countries, especially Bolivia and Venezuela, raises interesting questions about the rebirth of Christian Democracy. It is possible that Christian Democratic movements will be born or reinvigorated wherever and whenever the extreme Left or extreme Right gains popularity and power. However, there are many other factors that may affect the feasibility of Christian Democracy, such as poverty, inequality, the vitality of the Catholic Church, the extent to which the church cuts across class, and the extent to which it has been involved in education and the development of intellectuals and politicians. Of course, it is also possible that a new version of Christian Democracy will develop that will be influenced less by Catholic Christianity than by Evangelical Christianity, which has been growing in much of Latin America. For those interested in religion and politics, and more specifically in the feasibility of Christian Democracy, the twenty-first century promises to be an interesting period.

\textbf{DEMOCRACY, CONSOCIATIONAL}

The etymology of \textit{consociation} derives from the Latin for “with” and “society”: \textit{Consociatio} translates as “union” or “connection.” Today, consociation describes a “society of
societies.” The concept has some similarities with federation, but is not a synonym; consociations can exist in non-federal states.

Consociation was first developed in political theory by the Protestant jurist and philosopher Johannes Althusius (1557–1638). In the twentieth century the Dutch political scientist Arend Lijphart revived the term to describe political systems in which parallel communities, differentiated by ethnicity, language, religion, or culture, share political power while retaining autonomy (Lijphart 1968, 1977). He recognized his ideas had antecedents in the writings of the Austro-Marxists, Karl Renner, and Otto Bauer, and the Nobel laureate Sir Arthur Lewis. Lijphart argued that consociation is frequently invented by politicians negotiating political settlements. Contemporary examples of functioning or attempted consociations exist in Belgium, Bosnia and Herzegovina, Canada, the Netherlands, Switzerland, Northern Ireland, Lebanon, and Macedonia.

Consociations have three necessary features: executive power sharing among representatives of specific communities; proportional representation and allocation in governmental posts and resources; and community self-government, especially in cultural domains, for example in schools with different languages of instruction (O’Leary 2005). Fully fledged consociations empower representatives with veto rights over constitutional or legal changes.

Consociations are promoted to prevent, manage, or resolve conflicts, especially between communities divided by nationality, ethnicity, race, religion, or language. Consociationalists and their critics differ radically over their merits, and also over how consociations are established, maintained, or break down (McGarry and O’Leary 2004).

CRITICISMS OF CONSOCIATIONS

Some critics condemn consociational ideas as futile, and claim that consociational institutions have no (or no long-run) impact on deeply rooted, identity-based conflicts. Others attack consociations as perverse, claiming that they achieve the opposite of their ostensible purposes by institutionalizing the sources of conflict: By allegedly freezing the relevant collective identities, they encourage a politics of gridlock. Critics suggest that consociationalists are primordial pessimists who take people as they are, and not as they might be. These opponents prefer integration, the creation of a common citizenship and public sphere, and the non-recognition of cultural differences in the public domain. They also claim that consociation jeopardizes important liberal values, and that it leads to the irreversible formation of ethnic, communal, or sectarian parties. The use of quotas, affirmative action programs, and preferential policies weaken the merit principle, creating new injustices and inefficiencies. Others claim that consociation is undemocratic because it allegedly excludes opposition and inhibits alternations in power. Some claim it is elitist (Brass 1991, p. 339; Jung and Shapiro 1995, p. 273). Another argument denies the existence of consociations, claiming that there is no place that fits the criteria.

DEFENSES OF CONSOCIATIONS

Proponents argue that consociations cannot simultaneously be perverse—that is, reinforce and re-entrench ethnic antagonisms—and jeopardize all key liberal, democratic, and international values, and, all the while, be futile. The futility thesis is evidently the weakest criticism. It scarcely explains the passionate (and logical) criticisms of consociational theory and practice in the last three decades.

Consociationalists understand themselves as realists and counselors of necessary political triage. They believe that certain collective identities, especially those based on nationality, ethnicity, language, and religion, are generally fairly durable once formed. That does not mean that they are primordial or immutable, or that they are intrinsically desirable. But such durable identities are often mobilized in a politics of antagonism, especially during the democratization of political systems, and cannot be easily transcended. Politicians, parties, and communities certainly interpret their histories and futures through narratives, myths, and symbols, but they may have realistic rather than merely prejudiced appraisals of past group antagonisms. Consociationalists maintain that it is their critics—“social constructivists” and certain liberals and socialists—who are too optimistic about the capacities of political regimes to dissolve, transform, or transcend inherited collective identities. Consociationalists question the cosmopolitan protestations of many anticonsociationalists, who may cloak a partisan endorsement of one community’s identity and interests (into which others are to be encouraged to integrate or assimilate, in their own best interests).

The case for power sharing is advanced on grounds of necessity. Consociation provides good incentives for cooperation—a share in power. Consociationalists do not embrace cultural pluralism for its own sake. Sometimes the effective choice is between consociation and much worse alternatives: armed conflict, genocide and ethnic expulsion, imposed partition, or control by one group or coalition. The real choice in many deeply divided regions is therefore between consociational democracy and no (worthwhile) democracy—or breakup. The target of consociational criticism is integrationism and majoritarian democracy, which only work well, consociationalists argue, as political recipes in societies that are already homogeneous, or in immigrant states where immigrants are expected to integrate.
Consociationalists are skeptical about the current celebration of civil society as the (or even a) vehicle of transformation, peace making, and peace building. In divided places there is often more than one society, and their relations may be far from civil. Those who embrace a politics of deliberative democracy are reminded that deliberation takes place in languages, dialects, accents, and ethnically toned voices. Consociationalists respond to left-wing critics by observing that consociational ideas are present in the more thoughtful socialist traditions (Bauer 2000; Nimni 2004), and by observing how working-class and popular unity have been rendered hopeless by national, ethnic, religious, and communal divisions. Within consociational arrangements, trust may develop that may enable wider working-class or popular unity behind the welfare state or other forms of distributive politics.

Consociationalists therefore are friends of democracy, but critics of its palpably inappropriate versions in deeply divided places. They want majorities rather than the majority, or the plurality, to control government. Elite bargaining and adjustment should be designed to achieve widespread consensus—to prevent the possibility that democracy will degenerate into a war of communities. They endorse a politics of accommodation, of leaving each group to its own affairs where that is possible and widely sought—"good fences make good neighbors" (Esman 2000; Noel 1993, pp. 55–56). Consociations protect the basic natural rights of individuals and communities—especially the right to exist.

Consociationalists argue positively for consociation, not just by pointing to the horrors of the alternatives. Consociation provides autonomy for communities, and enables sensible shared intercommunity cooperation. It offers a more inclusive model of democracy—more than a plurality or a majority influence or control of the executive. More than a majority get effective "voice." Consociation does not eliminate democratic opposition, but enables such divisions and oppositions as exist to flourish in conditions of generalized security. Nothing need preclude democratic competition within communities, and turnover of political elites, and shifts of support between parties. In a liberal consociation nothing blocks the voluntary dissolution of historic identities if that is what voters want.

**TYPES OF CONSOCIATIONS**

It is a fallacy to suppose that consociation mandates that governments be wholly encompassing, grand coalitions of all communities (O'Leary 2005). One should distinguish among complete, concurrent, and "pluralitarian" consociational executives. In a complete consociation, all parties and all groups are included in the executive and enjoy popular support within their blocs. This is the rare case of the grand coalition, which may indeed preclude effective opposition, and may be made necessary by wartime conditions or postconflict state-building. In concurrent executives, by contrast, the major parties, which enjoy majority support within their blocs, are included within the executive, but opposition groups exist in parliament and elsewhere. In "pluralitarian" executives, the major communities may be represented by their strongest parties in the executive, but one or more of these parties may enjoy just plurality support within its respective bloc. What matters, therefore, is not the wholesale inclusion of all, but meaningful, cross-community or joint decision making within the executive. This clarification resolves a recurrent misunderstanding that all consociational practices preclude opposition.

Consociational arrangements may facilitate greater justice. Groups govern themselves in agreed domains of autonomy. Distributions that follow proportional allocations may be very fair: to each according to their numbers. There is a correlation between numbers and potential power that makes such distributive justice likely to be stable and legitimate. Consociationalists need not endorse the view that justice is "each according to their threat-advantage," but in some cases proportional allocations of public posts and resources are regarded as fair distributions, and will be robust as a result.

Consociationalists observe that consociations occur without their urgings. They are reinvented by politicians as "natural" creative political responses to a politics of antagonism. Politicians, Lijphart observes, invented consociational institutions in the Netherlands in 1917, in Lebanon in 1943, in Malaysia in 1958, and in Northern Ireland in 1972 (Lijphart 1990, p. viii) and again in 1998 (McGarry and O'Leary 2004, 2007). They were re-invented by American diplomats to end the war in Bosnia and Herzegovina at Dayton in 1995; by Lebanese politicians with external promptings in 1989; and by European Union diplomats in promoting the Ohrid agreement between Macedonian Slavs and Macedonian Albanians. The United Nations and the European Union have been trying to mediate a consociational and federal settlement in Cyprus. Within academic political theory, many contemporary multiculturalists advance consociational agendas, including inclusivity (cross-community power sharing), quotas (proportionality), and group rights (autonomy and veto) (Kymlicka and Norman 2000). The rival evaluations of consociation are unlikely to be resolved. They probably are not amenable to decisive falsification or verification. Anticonsociationalists fear consociation will bring back racism, fundamentalism, and patriarchy. Consociationalists fear integrationists will provoke avoidable wars and are biased toward dominant communities (McGarry and O'Leary 2004).
with which this debate rages attests to the influence of consociational thought.

Exponents of consociation, when their case is put carefully, successfully rebut the wilder charges made against their positions. Consociations are difficult to love and celebrate—even if their makers often merit intellectual, moral, and political admiration. They are usually the product of cold bargains, even if they may be tempered by political imagination. As for the explanation of consociations, although significant preliminary work has been done, a comprehensive comparative historical analysis of consociational settlements and their outcomes remains to be completed.

DEMOCRACY, INDICES OF

In order to document democratic development, a number of indices of democracy have been developed. These indices are formulated in a variety of ways, yet most are basically oriented to political, liberal democracy—what the political scientist Robert Dahl has called “participation and contestation” (Dahl 1971). Relatively high statistical correlations on the aggregated level also point to a far-reaching unity of viewpoint among those designing the different indices. The correlation coefficient (r) tends to lie at the 0.75–0.95 level (0.00 representing no concordance; 1.00 complete concordance). At the same time, there are differences—both conceptual and methodological—that make it significant which index is chosen. Experience has shown, namely, that in certain cases the choice of index can influence the results (Elkins 2000; Casper and Tufis 2003).

As a rule, extreme differences among countries (e.g., between Australia and Saudi Arabia) will register in much the same way no matter what index is used. Where more modest differences are concerned, however, the coding becomes more arbitrary, especially at lower or medium levels of democracy. It is likely, therefore, that changes over time will be registered differently by different indices. When studying gradual changes in the level of democracy,
the results could, to a substantial degree, reflect which index is used (Hadenius and Teorell 2005).

The choice of index, in other words, is not trivial. Hence, it is important to account for the way they are constructed. One difference concerns what prime aspects of democracy are actually measured. Some indices are based on a broad range of criteria, which are aggregated into a scale. Freedom House (FH), which is a frequently used index, is a typical example. It includes an extensive checklist of political rights (related to elections) and civil liberties, which are certainly relevant. However, it also includes certain criteria that could be seen as less relevant, such as free enterprise, property rights, and lack of corruption. The other leading index, Polity, has a more limited focus. It accounts for a number of electoral requisites, but pays no heed to political freedoms.

A few other indices deserve to be mentioned. Reich applies criteria that relate both to elections and political freedoms, whereas Vanhanen and Alvarez et al. are more constrained. Vanhanen looks at electoral participation (which is a strongly contested indicator) and the share of parliamentary seats for the governing party, while Alvarez et al. is concentrated on a fairly narrow set of electoral criteria.

One question that has occasioned controversy has to do with dichotomous versus continuous measures of democracy. The main argument in favor of the dichotomous approach (which distinguishes only between democracies and nondemocracies) is that this divide is the most essential one. The main counterargument is that this is too rough an assessment, and that it therefore misses more graded differences. Among the indices mentioned, only Alvarez et al. is dichotomous in character.

Indices also differ with respect to methodological qualities, such as how the operational measures have been chosen and what rules of coding and aggregation have been applied. It is important that the transformation of the data be openly displayed, so that the process can be replicated and made the subject of both testing and alternative coding and aggregation.

Polity, Vanhanen, and Alvarez et al. are generally held to meet high methodological standards, especially with respect to transparency. The construction of the Freedom House scale is a more concealed process, while Reich is even more problematic in this respect, for it provides almost no information about the operationalizations and the coding rules applied.

On balance—considering both conceptual and methodological aspects—Polity and Freedom House are the most useful indices. Comparing these indices for possible biases (which have been argued to exist), it turns out that they do not differ with respect to region, religion, or colonial background. But the type of regime does matter, at least in some respects. Freedom House treats traditional monarchies more favorably, while Polity is generally more “dichotomous” in character (most cases are located at the top or the bottom of the scale). Polity therefore applies greater rewards to democratic improvements. In addition, Freedom House is more concerned about political violence and repression, while Polity puts stronger emphasis on electoral performance.

It seems that in most instances in the 1970s and 1980s, Freedom House tended to overestimate the level of democracy, whereas Polity underestimated it. During the 1990s, however, it was the other way around: Freedom House made relatively strict assessments, to the effect that democracy tended to be underrated. The opposite held for Polity. An average score, therefore, based on the two indices, seems to give the most accurate assessment.

DEMOCRACY, RACIAL
The ideological construct referred to as the “Myth of Racial Democracy” continues to constitute the central framework for understanding the “racial commonsense” in Brazil, as well as in much of Latin America. The essence of this myth is contained within a traditional allegory addressing the origins of Brazil’s population, the “fable of the three races” (Da Matta 1997, p. 71). This fable holds that the Brazilian nation originated from three formerly discrete racial entities, Europeans, Africans, and Indians. These “races” subsequently mixed, each contributing to the formation of a uniquely Brazilian population, culturally and biologically fused.

The scholar Gilberto Freyre is credited with popularizing the notion of racial democracy in Brazil in the 1930s in his work New World in the Tropics: The Culture of Modern Brazil (1959). Confronted with scientific racism beliefs in the superiority of a white “race” and that mixed blood created degeneracy, Freyre proposed instead that “cross-breeding” produced hybrid vigor in humans, thereby enabling a bright future for the otherwise condemned dark Brazilian nation. He emphasized, for example, an uncommon flexibility on the part of Portuguese colonizers that made possible extensive miscegenation and claimed that mixed Brazilians were giving birth to a new meta-race, constituting a new world in the tropics.

The result of the Brazilian racial fusion, according to Freyre, was an “ethnic democracy, the almost perfect equality for all men [sic] regardless of race or color” (p. 7). In reality, Brazil is stratified along color lines, and Freyre’s academic musings reflect a romanticized view. His vision suggests a serious disjuncture between “ideal” versus “real” culture, between what Brazil is supposed to, or even said to, look like and how it actually is. Color or racial characteristics clearly correlate with lower socioeconomic status and disadvantaged life chances in general in Brazil. Individuals of varying degrees of African descent historically and in modern times occupy the lower rungs of the color hierarchy. The disparities along racial lines are produced and perpetuated by both historic and contemporary factors. Among the former is the early uneven industrialization among Brazilian states coupled with the concentration of non-whites in underdeveloped regions. Prominent among the contemporary factors is the continuation of negative black stereotyping that reverberates in countless areas, resulting in poorer educational experiences, police profiling and abuse, and discrimination in the labor market.

In this context marked by racial inequality, a majority of researchers view the racial democracy or miscegenation imagery as fostering a false conception of the reality of Brazilian racial dynamics, leading to the denial of racial discrimination. The myth has been described, for example, as an ideology of nondiscrimination and the prejudice of not having prejudice. This denial of racial discrimination on the part of both white and non-whites, then, is generally understood as the defining element of the myth.

In addition to masking racism, the Brazilianist literature further faults this construct for discouraging positive black racial identification and for neutralizing support for antiracism strategies. These two latter elements are believed to be highly correlated, as robust racial identities are generally considered a sine qua non of antiracist mobilization. In Brazil, racial subjectivity is diffuse, diluted in part by a traditional focus on ambiguous classification schemas. Furthermore, there has also been little history of the type of mass mobilizations against racial inequality that one might expect in such a context. Hence, participants in Brazil’s modest but growing black movement struggle to foster black racial identity formation among the masses at the service of antiracism.

Some researchers, however, question this wholly negative stance towards the myth of racial democracy. Rather than viewed primarily as an empirical description of racial dynamics characterized as “colorblind,” as elites have traditionally argued, the myth may instead constitute a moral high ground common to non-elite Brazilians that both recognizes and repudiates discrimination based on “race.” In fact, some newer research demonstrates that not only is there a keen awareness of racial discrimination in Brazil on the part of whites and non-whites alike, but there is also substantial support for antiracism measures. Hence, researchers argue that this racial fusion myth may be harnessed in ways that promote subordinate populations; the myth endorses the utopian dream of a less discriminatory society and thus can act as a charter for social action. Viewed as a positive cultural value, Roberto Da Matta wrote that we should “… elevate the myth of racial democracy as a patrimony that is capable of helping Brazil in … honoring its commitment to equalitarianism” (1997, p. 74).

In the end, myths are not necessarily untruths or statements of truth; rather, they are part of belief systems justifying specific cultural values and social rules. They can have a powerful impact on individuals because they communicate and reinforce particular commonsense understandings. The myth of racial democracy will continue to be scrutinized as long as Brazil is characterized by a disjuncture between “ideal” and “real” culture, between

rational democracy and racial inequality. It is clear that higher rates of racial intermarriage do not in and of themselves ensure a society beyond the reach of racial discrimination.

**DEMOCRACY, REPRESENTATIVE AND PARTICIPATORY**

Democracy was born in the Western world in the form of participatory democracy, making the term participatory democracy redundant. The word participatory discloses the core meaning of popular sovereignty as self-government. In the original ancient Greek meaning, *demo-kratia* (“rule of the demos,” or “tribes” into which the Athenian people were divided) entailed engaged citizenship and regular participation. In modern times, however, when democracy has become associated more closely with representation, accountability, and a form of indirect government in which the people select the rulers rather than ruling themselves, participatory democracy has come to be seen as an alternative form of democracy. Consequently participatory, or direct or “strong,” democracy and representative democracy have evolved into conceptual antonyms: two fundamentally distinctive forms of democracy rooted in contrary understandings of popular sovereignty as direct self-rule by the people and indirect rule by circulating elites chosen by the people, who otherwise remain outside government.

**PARTICIPATORY DEMOCRACY AND REPRESENTATIVE DEMOCRACY**

In principle all democracy is to a certain extent participatory. Every democratic system is rooted in an act of original consent through a popularly ratified social contract or constitution as well as ongoing popular input in the form of periodic elections. To this extent, to say that democracy is consensual is to say that it is participatory. In the modern era, however, participatory democracy implies much more than original consent or periodic elections. It denotes extensive and active engagement of citizens in the governing process, often through participatory devices such as initiatives and referenda, and emphasizes the role of the citizen as an active agent in self-legislation and a real stakeholder in governance.

This is in stark contrast to representative democracy, in which the citizen becomes a passive client of government, a watchdog to whom the government remains accountable but otherwise ignores, and a periodic elector responsible for selecting those who actually govern. Philosophers of participatory democracy such as Jean-Jacques Rousseau (1762) and Robert Michels (1911) have understood this “thin” representative construction of democracy as contrary to the core meaning of democracy. When there is representation, the democratic principle is nullified. In Michels’s terms, under representative democracy liberty can be said to disappear along with the ballot when it is dropped into the box.

**HISTORICAL GROWTH OF POLITICS**

The transition from direct democracy to representative democracy was dictated at least in part by historical changes in the nature and scale of society. Democracy was born in and designed for small-scale societies: towns, poleis, principalities, and city-states of the kind found in ancient Greece, early modern Europe, and pre-Revolutionary America. In such settings active participation by citizens in governance could be seen as synonymous with democracy, both desirable and practicable. However, the transformation of city republics into larger states and empires (Rome, for example, as it moved from a town-based republic to a continental empire) created novel constraints and revealed how early direct democracy was bound by limiting conditions, such as simplicity of manners and interests, relative homogeneity of culture and religion, and a small demographic and geographic scale that allowed the citizenry to meet in common in a public place. The ideal population was perhaps five hundred to five thousand, and the maximum size was approximately twenty thousand citizens: the number of active residents engaged in politics in Athens during the Periclean Age in the mid-fifth century BCE. Aristotle had
suggested that democracy could exist only on a territory a man could traverse on his way to join a democratic assembly in a single day.

The increase in scale that came with the evolution of towns into cities, then city-dominated provinces, and finally nation-states consisting of cities and provinces bound by nationalism mandated a reconsideration of democratic principles. If democracy entailed participation by all citizens in basic lawmaking, as Rousseau had insisted in the Social Contract (1762), the scale of capital cities such as Paris, Lisbon, and London ruled out effective participatory democratic rule and thus, for Rousseau, legitimate democracy. The American founders implicitly recognized that critique by arguing that a republic of potentially continental extent could be ruled only by a popular sovereign willing to be represented in the actual governing process. To Rousseau and his allies, that was an impossible compromise, for as Immanuel Kant had argued, autonomy demands self-legislation, and hence only those who govern themselves directly can be said to be free.

AMERICAN REPRESENTATIVE DEMOCRACY

In American representative democracy the tensions between direct popular government and indirect rule by chosen surrogates became evident, for the American representative principle was not merely a pragmatic way to preserve democracy in large-scale societies but also implied a critique of direct democracy. Direct popular rule risked enthroning not merely the popular sovereign but an incompetent and impassioned mass: a mob or, in French, a foule.

Representation had the virtue not only of facilitating popular sovereignty in large-scale settings but also of placing a filter between the masses and prudent or “good” government. Representatives had the obligation not only to represent the people’s will but also, in Edmund Burke’s terms, to filter it through and subordinate it to their own prudent judgment. Elected representatives could act in the name of the interests of the people as they understood those interests rather than being bound by the people’s “mandate” based on their own often faulty understanding. Even the popular right to choose representatives might be delegated prudently to other wise electors, as was meant to happen with the Electoral College, through which, in the first years of the American Republic, both senators and a president were to be chosen.

Behind the Madisonian distrust of direct democracy lies distrust of all popular power. Even the ancients worried that, just as aristocracy could deteriorate into oligarchy, democracy could morph into ochlocracy, Aristotle’s term for a people’s tyranny. Although the spirit of modern representative democracy is not antidemocratic, its spirit is cautionary and skeptical about majority rule, mirroring the skepticism about representation that is inherent in direct democracy. If power is dangerous, popular power is more dangerous because it has a righteous legitimacy. Indirect rule thus becomes a check on popular power consistent with the rule of law and constitutional limits on absolute power, especially when that power is popular.

CIVIC EDUCATION

Participatory democrats are cognizant of the critique of popular government as a euphemism for the rule of the passions—the sovereignty of the mob over cool reason as embodied in laws—and for that reason have focused on citizen (civic) education. Historical arguments about direct democracy have been conducted as arguments about education. Plato’s Republic is an argument on behalf of aristocratic education that denies that the majority has the capacity to govern. Rousseau’s philosophical educational novel Émile is an essay on democratic education.

Later democrats from Thomas Jefferson to John Dewey rested their case for democratic participation on the efficacy of democratic education. Dewey’s primary work on democracy is titled Democracy and Education (1954), and Jefferson was persuaded that in the absence of universal education for citizens, democracy could not work. Hence he deemed his work in establishing the University of Virginia (featured on the inscription he prepared for his tombstone) as more important in the long term than his presidency. The logic behind the Declaration of Independence and the Bill of Rights was tied closely to the logic of civic education. Rights belonged to everyone but could be exercised only by those schooled in citizenship. In 1840 Alexis de Tocqueville spoke of the “apprenticeship of liberty,” the “most arduous” of all apprenticeships, as a precondition of prudent democratic government.

Classical participatory democrats agreed that popular passions had to be filtered if popular government was to succeed, but they believed that the filter should be within the heads of citizens, and that entailed intensive citizen education. For the participatory or strong democrat, democracy means the government of citizens rather than merely the government of the people. In this formulation citizens are as far from ordinary people as public-thinking and civic-minded communitarians are from self-absorbed, narcissistic consumers of government services.

It is here that participatory democracy can be associated closely with deliberative democracy. To act as a citizen is not merely to voice private interests; it is to interact and deliberate with others in search of common ground and public goods. The aim of participation is not merely
to express interests but to foster deliberation and public-mindedness about interests. When Jefferson suggested that the remedy for the ills of democracy was more democracy, he intimated that democracy was deliberative and involved learning. Modern experiments in deliberative democracy such as those of James Fishkin (1991) have demonstrated that citizens can change their minds and become more open to public goods when exposed to deliberative procedures.

THE ROLE OF TECHNOLOGY

Fishkin's deliberative poll experiments utilized the new electronic technologies in ways that suggest that those technologies may help create conditions conducive to direct democracy, affording large-scale societies some of the democratic possibilities of small-scale townships. On the World Wide Web the world becomes a village, and physical communities that are ruled out by size or distance can be reestablished as digitally convened virtual communities. If democracy depends on association and communication, digital technologies that facilitate them become obvious tools of democracy. Presidential elections in the United States have offered opportunities for interaction among citizens, such as “meet-ups,” that give a participatory dimension to classical representative electoral campaigns.

The history of democracy began with forms of engagement and participation that were dependent on small-scale township government. Over time systems of representation were tailored to changes in social scale and an increasing distrust of popular rule. As the scale of potential governance becomes global, new technologies have the potential to reestablish forms of local self-rule that have been deemed outmoded, completing the paradoxical circle of the history of democracy.

DEMOCRATIC CENTRALISM

In the Marxist literature, democratic centralism refers to the organization of a Leninist party that allows members participation and voice, but compels them to follow the party line once a decision has been made. A more contemporary (and liberal) meaning of the term, which is the one discussed in this entry, refers to democratic countries that are organized along unitary lines or that are characterized by a high degree of fiscal, political, or administrative centralization.

Centralization is one of the distinguishing features of the modern state. While some European proto-states before the sixteenth century and the great empires of Asia successfully extended their rule over large territories, those political organizations were decentralized arrangements, characterized by a great deal of local autonomy in, for example, the financing of the state through tax farming or the exercise of political authority through satrapies, tributary provinces, and other accommodations of local rule. A fundamental shift occurred in Europe in the modern era, particularly during the eighteenth century, as nation-states were pressed to centralize authority in order to collect sufficient revenues to wage increasingly expensive wars. Alexis de Tocqueville (1805–1859) can be credited as the earliest theorist of democratic centralism. Perhaps the most important aspect of his analysis was to note that government capacity is endogenous to centralization: to the extent that administration becomes more centralized, local authorities become less empowered and more ineffective.
Early democratic experiences were both centralized, as in France and England, or highly decentralized, as in the United States and Switzerland. Hence there is no necessary link between centralization and democracy. Democratic centralism is often equated with a unitary, as opposed to a federal, form of government. However, William Riker (1964) noted that the survival of the United States as a political unit required the creation of a centralized federalism, which could enhance the territorial scope of the country while allowing it to confront external military threats. Thus, a link between centralization and the threat of war was present in the early history of the United States, as well as in the histories of the other federations in Europe and Latin America.

In both democratic and authoritarian countries, centralization (measured through the share of fiscal resources controlled by the national government, as compared to provincial or state and local governments) increased in the course of the nineteenth and twentieth centuries. However, between the 1930s and the peak of fiscal centralization observed around the world in the 1970s, local and intermediate levels of government in democratic regimes retained a larger share of revenue and expenditure authority than their authoritarian counterparts.

After the 1970s, a trend toward decentralization swept both advanced industrial democracies and developing countries. Decentralization has often been accompanied by the introduction of elections at the subnational levels of government, and the timing of decentralization has often coincided with democratization. This has led many observers to believe that centralism is incompatible with democratization. However, democratic countries show variations in fiscal, political, and administrative centralization through time, depending on the demands placed by citizens on various levels of government. Thus, there is no necessary link between decentralization and democracy.

DEMOCRATIC PARTY, U.S.
The Democratic Party is the oldest, continuously existing political party in the world. It is one of the two major political parties in the two-party system of the United States of America, and has nominated and helped to elect such internationally famous presidents as Thomas Jefferson, Woodrow Wilson, Franklin D. Roosevelt, and John F. Kennedy.

ORIGINS
The Democratic Party, previously named the Democratic-Republican Party, traces its origins to the Anti-Federalists. The Anti-Federalists initially opposed the ratification of the U.S. Constitution during the 1780s because of their concern that it would create an excessively powerful national government dominated by bankers and threaten states' rights. After the Constitution was ratified, the Anti-Federalists emphasized a strict interpretation of the Constitution so that states' rights and civil liberties would be protected from the new national government. Led by Thomas Jefferson and James Madison, the Anti-Federalists formally named and organized the Democratic-Republican Party in 1798. The Democratic-Republican Party often opposed the Federalist Party. Founded by Alexander Hamilton and John Adams, the Federalist Party favored a stronger national government, limited states' rights, a national bank, a pro-British foreign policy, a tight money supply, and high tariffs to encourage the development of American manufacturing. These Federalist policies dominated the presidencies of George Washington (1789–1797) and John Adams (1797–1801).

From the election of Jefferson as president in 1800 until the election of Abraham Lincoln, a Republican, in 1860, most presidents during this era were Democrats. The Democratic-Republican Party officially renamed itself the Democratic Party in 1844. The Democratic Party experienced a sharp increase in membership and electoral strength during and shortly after the presidency of Andrew Jackson (1829–1837). The so-called Jacksonian Democrats claimed that the Democratic Party was “the party of the common man.” They asserted that their policies and ideas, such as less federal regulation of the economy, lower tariffs, stronger states’ rights, opposition to the national bank, and stronger voting rights for poor white men, benefited the common man by increasing his political and economic power against the Whig Party and northern business interests.

Although the Democratic Party succeeded in attracting more voters who were Irish or German immigrants, urban laborers, and frontier settlers from 1828 until 1860, most of its voting strength remained in the South.
Consequently, the Democratic Party became severely divided and weakened by the issues of slavery and the South’s secession from the United States in 1861. While most Southern Democrats favored secession and the creation of the Confederacy, most Northern Democrats either favored accommodation and compromise with the Confederacy or supported the Union war effort led by President Lincoln (1861–1865).

REPUBLICAN DOMINANCE:
1860–1932
Established during the late 1850s from remnants of the Federalist and Whig parties, the Republican Party emerged as the new, second major party in the United States. It elected all but two presidents, usually controlled Congress, and dominated American national politics and domestic and foreign policies from 1860 until 1932 when Franklin D. Roosevelt, a Democrat, was elected president. Even during brief periods when the Democratic Party elected presidents Grover Cleveland (1885–1889, 1893–1897) and Woodrow Wilson (1913–1921) and occasionally controlled Congress, it was often divided between its multiethnic, urban northern wing and its mostly rural, white, Protestant, southern wing. The party’s southern wing dominated Democratic membership in Congress and decisions at Democratic national conventions.

In an effort to co-opt the anti–big business, agrarian economic protest movement known as Populism, the Democratic Party nominated William Jennings Bryan for president in 1896. Bryan was the Populist Party’s presidential nominee in 1892. However, many conservative Democrats and northern laborers perceived Bryan as a dangerous rural, economic radical. Many of them voted Republican in 1896 resulting in a long-term Republican realignment within the two-party system.

THE WILSON PRESIDENCY AND
THE 1920s
Although Woodrow Wilson was elected with only 45 percent of the popular vote in 1912, Wilson managed to unite most Democrats in Congress concerning his foreign policy in World War I and his domestic policies of improving child welfare and labor conditions, reforming the banking system, and supporting women’s suffrage. During the 1920s, however, the Democratic Party became more divided over such cultural issues as the national prohibition of alcohol, restrictive immigration laws, the Ku Klux Klan, and the Catholic faith of Al Smith, the Democratic presidential nominee in 1928. Consequently, the Republicans easily won the presidential elections of 1920, 1924, and 1928.

The Great Depression, which began with the stock market crash of 1929, resulted in high unemployment, deflation, bank failures, and widespread economic suffering. The Democrats became more united on economic issues and blamed Republican policies for causing or worsening the Great Depression. Attracting the votes of many alienated Republicans and independents, the Democratic Party easily won control of the presidency and Congress with Franklin D. Roosevelt as its presidential nominee in 1932. Collectively known as the New Deal, Roosevelt’s most popular economic and social welfare policies included the Works Progress Administration (WPA), the Social Security Act of 1935, legal rights for labor unions, agricultural price supports, rural electrification, and stricter federal regulations on banks and the stock market.

THE 1932–1936 DEMOCRATIC
REALIGNMENT TO THE CIVIL
RIGHTS ERA
In the 1936 federal elections, Roosevelt was reelected with 62 percent of the popular vote, carried all but two states in the Electoral College, and helped the Democratic Party to increase its majorities in Congress. For the first time since 1856, most voters were Democrats. The 1932 and 1936 elections were a realignment of the two-party system establishing a long-term Democratic majority among voters. This enabled the Democratic Party to win most presidential elections, usually control Congress, and dominate foreign and domestic policymaking until 1968.

President Harry S. Truman, Roosevelt’s Democratic successor, won the 1948 presidential election despite the defection of some anti–civil rights southern Democrats led by Governor J. Strom Thurmond of South Carolina. Commonly known as the Dixiecrats, the States Rights Democratic Party nominated Thurmond for president in 1948. The Dixiecrats opposed Truman’s civil rights bill, his desegregation of the military, and the increasing support of northern Democrats for federal civil rights policies that would protect African Americans from racial discrimination and end racial segregation.

For the next twenty years, the Democratic Party was increasingly divided over the issue of federal civil rights for African Americans. The narrowness of Democrat John F. Kennedy’s victory in the 1960 presidential election was partially caused by the unpopularity of his pro–civil rights positions among southern Democrats. Likewise, despite his landslide victory in the 1964 election, Lyndon B. Johnson, Kennedy’s successor and a southern Democrat, failed to carry most states in the Deep South because of his support for civil rights.

By the late 1960s, the Democratic Party was bitterly divided over civil rights, the anti-poverty programs of the Great Society, the Vietnam War, and the selection of its presidential nominee for the 1968 election. In 1968,
events such as the assassination of presidential candidate Robert F. Kennedy, the violence and disunity of the Democratic National Convention in Chicago, and the unpopularity of Johnson and Vice President Hubert H. Humphrey among antiwar Democrats plagued the Democratic Party. Humphrey, the Democratic nominee, narrowly lost the 1968 presidential election to Republican nominee Richard M. Nixon as most white voters supported either Nixon or George C. Wallace, an anti–civil rights southern Democrat.

**REPUBLICAN DOMINANCE: 1968–1992**

From 1968 until 1992, the Republican Party won five of the six presidential elections and controlled the Senate from 1981 until 1987. Historians attribute the narrow Democratic victory of James E. Carter in the 1976 presidential election to economic problems and the damaging effects of the Watergate scandals on the Republican Party. During this period, many middle-class white voters negatively perceived the Democratic Party, especially in presidential elections, as favoring excessive welfare spending and high taxes, weak on crime control, and ineffective in cold war foreign and defense policies.

**THE CLINTON ERA AND POST-2000**

In 1992 William J. Clinton, a Democrat, was elected president with 43 percent of the popular vote after defeating Republican president George H. W. Bush and Ross Perot, an independent candidate. Clinton portrayed himself as a moderate who was tough on crime and welfare dependency and would reduce the high budget deficit. The end of the cold war and the Persian Gulf War in 1991 had reduced the Republican advantage on foreign and defense policy issues. In 1996 Clinton became the first Democrat since Roosevelt to be reelected to a second term. With a Republican Congress, Clinton achieved moderate, compromised results in welfare reform and deficit reduction but unsuccessfully opposed his impeachment.

Al Gore, Clinton’s vice president, received approximately 550,000 more votes than George W. Bush, his Republican opponent, in the 2000 presidential election. But Bush won this election when the Supreme Court ruled that he had legitimately received all of Florida’s Electoral College votes. Despite growing public criticism of his policies in the Iraq War, Bush was reelected in 2004 after defeating John F. Kerry, the Democratic presidential nominee. Confronting a two-term Republican president and a Republican Congress, the Democratic Party began to discuss how to improve its voter appeal and reconsider its ideas and policy positions in order to win future presidential and congressional elections. In 2006 Democrats regained control of Congress.

**DEMOCRATIZATION**

Democracy has widely become the norm within the international community. To promote democracy around the world is not only a key goal of international organizations such as the World Bank, but it is also on the foreign policy agenda of many European and North American countries. Nevertheless, democracy is a notoriously vague and encompassing term. It is often used as a synonym of whatever is desirable in a state, such as good governance and democratic values of elites and citizens. Illustrative of the lack of consensus about its meaning are the results of a survey finding that 150 different studies used more than 550 subtypes of democracy (Collier and Levitsky 1997).

**CONCEPTS**

Despite this lack of consensus, most political scientists and policy makers use the minimalist definition of democracy described in Robert A. Dahl’s 1971 book, *Polyarchy*. According to this definition, democracy is a system of government in which citizens choose their political leaders during periodic free and fair elections, thereby giving those leaders the right to rule after the elections. There are two main theoretical dimensions of democratization: competition among political parties for the people’s vote on the one hand, and inclusive suffrage and political participation on the other hand. South Africa’s apartheid government (1948–1994) was competitive but not inclusive, because the vast (black) majority was excluded from the right to vote. Regimes in the People’s Republic of China and North Korea are inclusive but not competitive, because one political party dominates political life completely. Only regimes with both competition and inclusive suffrage can be classified as a (minimal) democracy.
Democratization is the process whereby a country adopts a democratic regime. Dankwart A. Rustow (1970) distinguished four different phases. During the first phase national borders, national unity, and a coherent national identity must emerge, before democratization can occur. The second “preparatory” phase is characterized by political conflicts between old and new elites in which the new ones demand more influence in national politics. During the “decision phase,” key actors, such as the political parties, must accept a fundamental set of democratic rules and practices. Finally, basic democratic institutions and the rules of the game are established in the “habituation phase.” Each phase is the result of different causal processes. Given their different causes, it is useful to separate them.

Moreover, scholars often distinguish the phases of “transition” to and “consolidation” of democracy from each other. Transitions are defined as the interval between the dissolution of the old regime and the installation of a new regime, while the essence of consolidation is in defining and fixing the core rules of democratic competition. It should be noted, however, that there is a huge debate about the exact meaning of both terms in the democratization literature (Schedler 1998).

**TRENDS OF DEMOCRATIZATION**

Democratization is a relatively recent phenomenon. Although some Greek city-states had democratic characteristics, modern—or minimal—democracy dates only from the late nineteenth century. Since the publication of Samuel P. Huntington’s influential 1991 study of democratization, *The Third Wave,* scholars have come to take for granted the notion that the spread of democracy has come in waves. A wave of democratization is defined as a group of transitions from nondemocratic to democratic regimes that occurs within a specified period and that significantly outnumbers transitions in the opposite direction.

During the so-called first wave of democratization between 1893 and 1924, New Zealand, Australia, the United States, and many countries in western Europe made a transition to democracy. The regime changes to authoritarianism during the second reverse wave after 1924 reflected the rise of the ideologies of communism and fascism. A second short wave began after World War II (1939–1945) and continued until approximately 1960. Allied occupation promoted the installation of democratic institutions in West Germany, Japan, and Finland. Costa Rica, Chile, and Uruguay were the Latin American states that adopted a democratic system during this period. There is no clear second reverse wave, but the 1960s and 1970s can better be described as an intermezzo, in which transitions to both nondemocratic and democratic regimes occurred (Doorenspleet 2000). In this period, for example, Colombia and Venezuela became democratic. By contrast, the polarized Chilean democracy was overthrown by a military coup led in 1973 by General Augusto Pinochet (1915–2006). Military coups in Uruguay and Argentina ended democracy in these countries as well.

The third wave began in southern Europe in the 1970s in Portugal, Greece, and Spain. Then it spread to Latin America—to Ecuador, Peru, Bolivia, Argentina, El Salvador, Uruguay, Honduras, and Brazil. This wave of democratization also affected some Asian countries in the late 1980s, such as the Philippines and South Korea. The so-called fourth wave since 1989 was overwhelming and global. At the end of the 1980s, the wave swept through Eastern Europe. The 1990s saw widespread rapid collapse of nondemocratic regimes in Africa, and more than a dozen democracies emerged. The decade after the cold war was a fruitful period for democratization around the world.

**EXPLANATIONS OF DEMOCRATIZATION**

Nevertheless, many countries remained authoritarian. So, why do some countries democratize whereas others do not? According to modernization theories, which became dominant in the late 1950s, democratization is less likely in poor countries. If less-developed countries are not able to undergo this political modernization process, it is caused by a low level of socioeconomic development in the country. Each less-developed country would have to follow the same path already traversed by the now developed and democratic countries. After the publication of Seymour Martin Lipset’s 1959 article, “Some Social Requisites of Democracy,” many statistical studies showed that there was indeed a positive correlation between development and democracy. India, with its democratic regime and low economic development, is always brought up as an important exception to this general pattern, though. Moreover, studies of the 1990s show that modernization theory can explain democratic consolidation, but not transitions to democracy (Przeworski and Limongi 1997).

As a reaction and alternative to the modernization approach, the dependency and world-system theories emerged in the early 1970s in Latin America (Bollen 1983). The underdevelopment of Latin America was attributable to its reliance on the export of primary products to the industrial states of the capitalist system, and it was argued that Latin America had been turned into a satellite of the capitalist metropolises of Europe and North America. This approach states that a country’s position in the world system, located in either the dominant rich core or impoverished subordinate periphery, is an important determinant of democracy. According to this approach, if
a country is not able to become democratic, this is due to external factors—rather than internal domestic factors.

In addition to economic development and international dependency, cultural influences, ethnic divisions, the type of religion, and historical institutional arrangements have been mentioned by researchers as important structural explanations of democratization. According to actor-oriented theorists, however, regime transitions are not determined by structural factors, but are shaped by what principal political actors do as well as by when and how they do so. In their 1986 study Transitions from Authoritarian Rule, Guillermo O’Donnell, Philippe C. Schmitter, and Laurence Whitehead abandoned their earlier structuralist perspective and began to focus on the role of elites. They emphasized that elite dispositions, calculations, and pacts largely determine whether or not an opening to democracy will occur at all. Strategic interaction between elites from the state (political parties, the military, and political leaders) and elites from the society (social movements, civil society groups, and intellectuals) establishes the mode of transition and the type of regime that emerges afterward. In “transitions from below” mounting popular pressures and mass mobilization eventually lead to regime change, while in “transitions from above” political and military rulers respond to crises by introducing democratic reforms whose timing and substance they hope to control.

Since the early 1990s, democratization scholars emphasize that the described approaches complement rather than contradict each other, and suggest that a comprehensive theory of democratization should include not only structural but also actor-oriented factors.

DEMOCRATIZATION AND WAR

Democratization processes seldom follow an easy, smooth path. On the contrary, violent conflicts and wars often occur in democratizing states. Conflict can be prevented more easily in very nondemocratic regimes on the one end (because these regimes are willing and able to suppress dissent) and in democratic regimes on the other end (because these regimes recognize minority rights and try to conciliate, thereby reducing dissatisfaction and conflict). Democratizing countries, however, are situated in a dangerous phase in which conflict is very likely.

Not all democratic transitions are dangerous, but the chance of war rises especially in those transitional states that lack the strong political institutions that are needed to make democracy work, such as an effective state and organized political parties (Mansfield and Snyder 2005). The most important reason for this is that political leaders try to use nationalism or ethnic identity as an ideological motivator of collective action in the absence of effective political institutions. Then politicians have the incentives to resort to violent nationalist or ethnic appeals, tarring their opponents as enemies of the nation or the ethnic group, in order to prevail in electoral competition. When political institutions are strong, though, war can be prevented. This is particularly crucial in ethnically divided countries. A stable democracy is impossible in a country without strong political institutions.

DEMOCRATIC TRANSITION

The term demographic transition originally described the major social shift that occurred in Western societies from the late nineteenth century to the 1930s. At that time,
European societies, and their settler offshoots overseas, moved with considerable speed from a high-mortality, high-fertility population regime to low fertility and low mortality, with major social consequences. This historic shift saw the decline of family size from approximately six children per family to fewer than two. The transition also provided the preconditions for women to move from the private sphere and constant childbearing to the public domain and the expanding industrial work force.

Explanations for this world-shaping change abounded, and a field known as demographic transition theory developed, which, while hotly contested, remains influential. Population trends, such as the post–World War II (1939–1945) “baby boom,” have shaken the theory of continuing fertility decline, yet it has remained remarkably resilient. It is clear now that demographic transition is a global phenomenon, not just a Western trend, and that since 1960 much of the world is exhibiting declining fertility, with sub-Saharan Africa probably the last to change. Most now accept that a second demographic transition is occurring (van de Kaa 1987), dating from the 1960s, as even lower birthrates, well below replacement level, prevail in several European and Asian countries. While many demographers expected that birthrates would reach the replacement level, and then plateau, now there is concern that some countries’ birthrates are so low that their societies will eventually shrink, possibly disappear.

The concern with demographic change has considerable implications for political and social decision making in relation to the family, the labor market, and immigration policy. Fertility decline has moved from being a preoccupation of demographers to a central concern for politicians and social commentators. It takes on a new urgency as low fertility leads to inevitable population ageing.

In the 1960s exponents of demographic transition theory in the West, fearful of a “population explosion,” particularly in the developing world, and eager to gain political advantage in a cold war climate, sought to apply the theory, with varying results, in developing countries through agencies such as the World Bank and the United Nations Fund for Population Activities. The birth control pill, adopted so centrally in the West, was originally funded to provide contraception in the developing world on the understanding that knowledge of birth control was all that was needed for fertility decline. Later, more considered approaches are based on the broader finding of demographic transition theory—that socioeconomic change is more likely to lead to reduced fertility.

HISTORY OF THE THEORY
Demographic transition theory is curiously paradoxical. While there is no general agreement as to its explanatory frameworks, it is constantly invoked as if there were. This is due in part to demography’s post–World War II desire to be a science and to establish a “grand theory” of population and fertility decline. Yet even in this quantitatively based discipline, wider intellectual currents have intruded: postmodernism and cultural and anthropological explanations have recently entered the field. Short-term theory is now the order of the day.

In 1937 Kingsley Davis (1908–1997), an early exponent of the theory, suggested that ultimately the reproduction of the species is incompatible with advanced industrial society. Thus he established the major framework of the theory, which held that socioeconomic development and modernization are major causal forces. It is this element of the theory that remains robust. In a 2006 volume titled Demographic Transition Theory, one of the most influential twentieth-century exponents, John C. Caldwell, argued that in industrial society the old values essential to agricultural societies—strong family, virginity, loyalty, legitimate births—are no longer necessary except as “social pacifiers.” Industrial society and, even more, postindustrial knowledge economies, need mobile, educated individuals unencumbered with babies and family ties.

Within the overarching model of socioeconomic change, there is no common acceptance of particular determinants of transformation, as different societies take varying paths to declining birthrates. The onset and tempo of mortality and fertility decline vary widely. Must a falling off in mortality precede a fertility decline? Are modern technologies of birth control essential or indeed sufficient? Is decline more likely in conjugal families (those based on husband, wife, and children) rather than the joint (extended) families of much of Asia and Africa? How critical are gender regimes? It is now overwhelmingly clear that women’s education is inversely related to fertility. The more highly educated women are, the fewer children they produce, with few exceptions. How critical is institutional change, such as government policy in relation to education, to welfare provision, and to legal frameworks (McDonald 2006)? What role does ideational change play—the decline of religious belief, the centrality of individuals and their entitlements, the significance of planning modern lives, women’s reproductive rights, and notions of consumption and leisure? All of these elements have played a significant part in variants of demographic transition theory.

Some countries (Japan, Singapore, Taiwan, as well as much of central Europe and southern Europe) now exhibit very low fertility, defined as continuing fertility under 1.5 births per woman on average, sometimes referred to as a birth strike. Most commentators agree that this is largely due to women working and to the inability of states to make women’s work and childbearing compatible. Does this low fertility foretell the future or is the
experience of the United States, which since the late 1970s has exhibited a rise to replacement-level fertility, an opposing model? How significant is mode of production versus changing ideas and attitudes? Dirk van de Kaa, an influential demographer from the Netherlands, maintains that cohorts of young people with common, postmodern, individualistic ideas are implicated, whereas Caldwell insists that mode of production is primary and that neoliberalism and the accompanying insecurity it produces in the workplace play a significant role in inhibiting births.

Some theorists have predicted that the creation of a world economic system where children are of no immediate economic value to their parents will inevitably lead to lower world population—a goal much desired by environmentalists. Others point out that in much of Asia and Africa, patriarchy, a regime that puts children and lineage before women’s rights, is still dominant and that fertility decline may not be inevitable. Prediction is always fraught, and an element that has been overlooked in much twentieth-century demography may well come back to haunt us. Secularization, the decline of traditional religious belief, is a key to changing Western fertility patterns. Yet any assumption that secularization will inevitably increase is risky in the light of resurgent fundamentalisms across all religious belief systems. Anthropological demography reminds us that we are not all rational actors, and that myth, superstition, and culture are all pervasive.

Between 1965 and 2000, the fertility (as measured by the total fertility rate) of both the developing world and the whole world nearly halved (Caldwell et al. 2006, p. 13). On the basis of the United Nations World Population Prospects (2004) and other findings, demographers have predicted that global population growth will almost come to a halt by 2050, “with the Earth having around 9 billion or fewer inhabitants” (Caldwell et al. 2006, p. 316). Higher and lower projections have been offered, the latter demonstrating population halving every two hundred years—surely an unacceptable outcome. With the rate of world population growth slowing, some are turning to issues of the composition of the population.

A third demographic transition has been proposed for Europe and the United States, one that sees the ancestry of some national populations being radically and permanently altered through high levels of immigration of people with distinctively different ethnic ancestry into countries with low fertility (Coleman 2006, p. 401). This is a radical departure from previous demographic transition theory in its focus on immigration. It demonstrates, however, the resilience of the theory. The demographic transition may well continue to surprise us.

DEMOGRAPHY
Demography is the scientific study of the size, composition, and distribution of human populations, and their changes resulting from fertility, mortality, and migration. Demography is concerned with how large (or small) populations are, that is, their size; how the populations are composed according to age, sex, race, marital status, and other characteristics, that is, their composition; and how populations are distributed in physical space (e.g., how urban and rural they are), that is, their spatial distribution (Bogue 1969). Demography is also interested in the changes over time in the size, composition, and distribution of human populations, and how these result from the processes of fertility, mortality, and migration.
The term *demography* is from the Greek *demos* (population) and *graphia* (writing). It is believed to have first appeared in print in 1855 in the book *Elements of Human Statistics or Comparative Demography* by the Belgian statistician Achille Guillard (1799–1876) (Borrie 1973, p. 75; Rowland 2003, p. 16).

Some demographers argue that demography is best treated as a subdiscipline or specialization of sociology owing to its organizational relationship with sociology (Moore 1959, p. 833). However, the organizational affinity in universities between demography and sociology is not universal. In some Eastern European universities, demography is organizationally linked with economics, and in some Western European universities, with geography. In many countries (e.g., China), demography is taught in a separate university department.

The American sociologist Kingsley Davis (1908–1997), who served at different times as president of both the Population Association of America and the American Sociological Association, wrote in 1948 in his classic sociology textbook, *Human Society*, that “the science of population, sometimes called demography, represents a fundamental approach to the understanding of human society” (1948, p. 551). The relationship between sociology and demography is hence a fundamental one: “Society is both a necessary and sufficient cause of population trends” (1948, pp. 553–554).

There are only two ways to enter a population, by birth and by in-migration. There are two ways to leave a population, by death and by out-migration. Thus, a population is often defined by demographers according to the specific needs of the research and researcher. Samuel Preston and his colleagues have written that the ‘term “population” refers to a collection of items, for example, balls in an urn. Demographers use the term in a similar way to denote a collection of persons alive at a specified point in time who meet certain criteria” (2001, p 1). For example, the population of interest may be that of students attending a specific university during a specific year. In this situation, the students are born (i.e., enter) into the population when they enroll, and they die (i.e., leave) when they graduate.

Generally, demographers use vital registration (birth and death) records to count births and deaths in a population to determine fertility and mortality rates. The more difficult demographic process to measure is migration because in most countries registration records are not maintained when persons migrate into or out of the population. Data gathered around the world from decennial census and sample surveys are also used by demographers to examine demographic and sociodemographic issues.

Demographic techniques allow for the calculation of population projections, which specify the future size of the population by utilizing specific assumptions about the parameters driving the future fertility, mortality, and migration of the population. Population projections for all the countries around the world are periodically calculated by demographers at the United Nations and other international organizations and are made publicly available. Such projections are often used by government agencies and private firms to plan the infrastructure of cities, such as the number of schools, hospitals, airports, and parks that would be needed in the future in order for the cities to be able to function properly.

Demography is concerned not only with the observation and description of the size, composition, and spatial distribution of human populations and the changes resulting from fertility, mortality, and migration. Demography is also concerned with developing explanations for why the demographic variables operate and change in the ways they do: That is, why do some populations increase in size and others decrease? Why do some become older and others become younger? Why are some more urban and others more rural?

One paradigm in demography, known as *formal demography*, uses only demographic variables, such as age and sex, as independent variables to answer the above questions. Another paradigm, known as *social demography*, uses such nondemographic variables as marital status, race, education, socioeconomic status, occupation, household size, and type of place of residence—variables drawn mainly from sociology, economics, psychology, geography, anthropology, biology, and other disciplines—to answer the questions.

To illustrate, formal demographers might address differences in populations in their birth rates and death rates by considering their differences in age composition or in sex composition. Younger populations typically have higher birth rates than older populations; and populations with more females than males will usually have lower death rates than populations with more males than females (Poston 2005). Social demographers might address the above differences in populations in their birth rates and death rates by examining differences among them in, say, their socioeconomic status. Usually, populations with high socioeconomic status will have lower birth rates and death rates than populations with low socioeconomic status.

Demographic data may be introduced to provide some perspective for distinguishing between these two approaches. Human populations have different levels of fertility. Countries thus differ with respect to their total fertility rates (roughly defined as the average number of children born to a woman during her childbearing years). In 2004 Poland and Romania had very low fertility rates of 1.2, among the lowest in the world. Conversely, Niger.
Guinea-Bissau, and Yemen had very high fertility rates of 8.0, 7.1, and 7.0, respectively—the highest in the world (Population Reference Bureau, 2004). Why do these fertility differences exist? Why do Niger, Guinea-Bissau, and Yemen have fertility rates that are so much higher than those of Poland and Romania? To answer this question, the social demographer would go beyond purely demographic issues of age and sex composition and would focus on the processes of industrialization and modernization.

Another example focuses on what demographers refer to as the percentage rate of natural increase/decrease, that is, the difference between the birth rate and the death rate. In 2004 both Russia and Bulgaria had a rate of -0.6 percent: that is, the difference between their crude birth and death rates was about -0.6/1000 or -0.6/100. In contrast, the rate in both Madagascar and Saudi Arabia was 3.0 percent. In these countries, the difference between their birth and death rates was 30/1000 or 3/100.

Why are these four countries growing at such drastically different rates? Why do Russia and Bulgaria have negative growth rates, and why do Madagascar and Saudi Arabia have positive rates? The formal demographer might develop an answer by considering the birth rates of these countries. The numbers of babies born per 1,000 population in 2004 in Russia, Bulgaria, Madagascar, and Saudi Arabia were 10, 10, 43, and 32, respectively. The latter two countries have higher rates of growth than the former two countries because their birth rates are so much higher. The social demographer would first consider the birth rate differentials, but would then go beyond this demographic consideration to an answer involving non-demographic factors that may be influencing the birth rates. Perhaps the economy has something to do with it (poorer countries have higher birth rates). Perhaps the level of industrialization of the country has an impact (the more industrialized countries generally have lower birth rates). Perhaps the role of women compared to men is having an effect (countries with more gender equity tend to have lower birth rates).

Whatever the reasons, the social demographer extends the answer beyond demographic reasons. Social demography is broader in scope and orientation than formal demography. Preston has noted, for example, that demography includes “research of any disciplinary stripe on the causes and consequences of population change” (1993, p. 593).

Given the impact of industrialization in the reduction of fertility and mortality and the international migration flows from less developed to more developed countries around the world, it is a common practice among demographers to observe separately the demographic processes in less developed countries from those in more developed countries. The issues that concern demographers often vary depending on the level of industrialization of each country. In less developed countries, high levels of fertility, high levels of infant mortality, a high prevalence of HIV/AIDS, and high levels of out-migration to more developed countries tend to be some of the main demographic concerns. In more developed countries, low fertility patterns, women having babies at later ages, populations with below replacement levels of fertility, and large numbers of migrants from less developed countries are some of the main issues being examined by demographers.

A frequent concern in demography is the extent to which changes in individual-level behavior have an effect on aggregate processes (Preston et al. 2001). For example, if it suddenly became normative for individuals in a population to become smokers once they reach a certain age, then the demographer would want to find out to what extent the life expectancy at age x would be affected, as well as the death rate for that population. Similarly, regarding fertility, if women in a certain country decided to have children at older ages, then the concern becomes to what extent such behavior can have an effect on the total fertility rate, on the growth rate, and on whether the population will be maintained at a replacement level of fertility (which in populations with low levels of mortality is around 2.1 children per woman).

Demographers also are often concerned with how social policy could impact the aggregate population processes. In China, for example, demographers have identified a relationship between the enforcement of fertility policies and increasing levels of social and economic development and the sex ratio at birth (Poston et al. 1997; Poston and Glover 2005). The sex ratio at birth is the number of males born per 100 females born and is around 105 in most societies. Since the 1980s in China it has been significantly above 105. In 2000 China’s sex ratio at birth was near 120. The rapid reduction of fertility in China, along with the long-standing preference for sons, has led to the selective abortion of female fetuses, and a sex ratio at birth above normal levels. As a consequence, in China there will not be enough women in the population for the next few decades for Chinese men to marry. This is a major effect of societal modernization and fertility-control policies (Poston and Morrison 2005).

Demographers do not always agree about the boundaries and restrictions of their field. John Caldwell stated the problem succinctly: “What demography is and what demographers should be confined to doing remains a difficult area in terms not only of the scope of professional interests, but also of the coverage aimed at in the syllabuses for students and in what is acceptable for journals in the field” (1996, p. 305).

Other demographers argue for a broader approach, noting that demography is not a specialization of sociol-
ogy, or of any discipline, but a discipline in its own right. Consider the definition of demography in the popular demography textbook Population: An Introduction to Concepts and Issues by John Weeks: Demography is “concerned with virtually everything that influences, or can be influenced by” population size, distribution, processes, structures, or characteristics (2005, p. 5).

It is no wonder that J. Mayone Stycos observed that “as a field with its own body of interrelated concepts, techniques, journals and professional associations, demography is clearly a discipline” (1987, p. 616). Caldwell also reached this conclusion, but more for methodological reasons: “Demography will remain a distinct discipline because of its approach: its demand that conclusions be in keeping with observable and testable data in the real world, that these data be used as shrewdly as possible to elicit their real meanings, and that the study should be representative of sizable or significant and definable populations” (1996, p. 333).

DEMOGRAPHY, SOCIAL

The field of social demography uses demographic data and methods to describe, explain, and predict social phenomena. It also measures the effect of social forces on population distribution. Distinct from formal demography, which focuses more generally on population composition and distribution, social demography investigates the social-status composition and distribution of a population.

DEVELOPMENT OF SOCIAL DEMOGRAPHY

Social demography emerged as an academic discipline in the United States over the course of the last half of the twentieth century. Kingsley Davis coined the term social demography in a 1963 paper (Heer 2005). Previously, the term population studies was used to denote the study of social status using demographic techniques. In 1970, Thomas Ford and Gordon DeJong published a textbook titled Social Demography, which included research exemplars in the field. In 1975 the first conference on social demography was held at the University of Wisconsin.
Social demography developed in the United States as an outgrowth of regular census data, the development of demographic techniques, an interest in scientific investigation, and a general curiosity concerning social issues. Institutionalized by the U.S. Constitution, the U.S. Census has received increased funding and been accompanied by increased research activity and scientific rigor with each succeeding decennium. This continuous expansion has offered rich datasets to researchers. Thus, the application of modern statistical methods to demographic data collection and analysis has increased the validity and reliability of demography in general.

Corollary to the development of demographic techniques was a glorification of scientific solutions to modern problems. Social issues came to be viewed as problems that could be solved scientifically. Social demography emerged as a prime tool to isolate, explain, and predict factors influencing social issues such as residential segregation, unemployment, and income gaps between status groups.

Sociology and social demography developed in tandem over the course of the twentieth century. Early social theorists utilized demographic data as empirical evidence of their claims. W. E. B. Du Bois, for example, chronicled the experience of the African American population at the end of the nineteenth century through the use of census enumeration data, independent surveys, and cartography. Robert Park and Ernest Burgess, along with many others within the Chicago school of sociology, later extended the use of demographic data to support sociological claims of urban growth and population distribution by socioeconomic status. In the late 1950s, Philip Hauser and Otis Duncan codified the connection of sociology and demography in their work Population Studies.

Beginning in the 1960s, training in social demography became formalized into academia. Research and training in the discipline developed at university centers such as Chicago, Wisconsin, North Carolina, and Michigan. Also, population research centers at Princeton, Brown, and the University of Texas contributed scholars and research to social demography.

CURRENT TRENDS IN SOCIAL DEMOGRAPHY

Charles Hirschman and Stewart Tolnay (2005) identify three distinct areas within the current state of social demography: (1) data collection and descriptive interpretation; (2) theory development and model testing; and (3) contextual analysis.

Data collection is a staple of social demography. Modern democracies and consumer economies rely heavily on reliable data and descriptive analyses to fit policies and services to their respective constituents and consumers. Indeed, demographic data and interpretation are ubiquitous in modern society. Politicians, business leaders, historians, and the media offer many, and often contradictory, interpretive reports based on social demographic data each day. Social indicators for income, labor, occupation, housing, immigration and migration, and family status are regularly collected, analyzed, and released to the public.

In addition to data collection and descriptive analysis, social demographers contribute to cumulative knowledge through theory development. Researchers use statistical models to isolate and compare the effects of variables on social phenomena. For example, the sociologist Otis Dudley Duncan was able to test and ultimately refute the “culture of poverty” hypothesis, which was a common theory of the economic disparity between African Americans and whites (1970). Using the demographic method of direct standardization, Duncan held constant the effects of occupation, education, parental status, mental ability, and many other factors affecting income. By varying only the race of the respondent, Duncan showed that black men earned 83 cents to every dollar earned by white men, even though no other significant differences between the groups existed. Race alone was responsible for the seventeen-cent differential, not culture-of-poverty variables such as “father’s education” or “family type.”

Finally, contextual analysis may be a promising area of development in the near future. Contextual analysis investigates the interaction of the individual and the demographic environment in which that individual is situated. The role of structural context on individual behavior is commonly accepted in sociology. For instance, research on “school effects” attempts to show the role of schools in the educational attainment of individual students. However, contextual-analysis reports in education reveal relatively small school effects once the individual’s variables are controlled. Until recently, contextual analysis has been hindered by conceptual and methodological constraints. However, recent developments in statistical methods and software may yield much future research in this area.

LIMITATIONS FACING SOCIAL DEMOGRAPHY

Although social demography enjoys a high status within the social sciences, there are limitations to its applicability. Not all changes that occur within a society are a function of population composition. For example, the mid-twentieth century baby boom occurred across all educational, age, and racial groups. Therefore, the common approaches social demographers use cannot isolate the source of the variation in fertility. The source of the variation in the case
of the baby boom was contextual: political and economic circumstances had changed greatly after World War II. The source of the variation in fertility did not, therefore, come from various segments of the U.S. population.

Another limitation for much social demographic research is that it is oriented towards disproving false hypotheses. False hypotheses are uncovered by statistically revealing the amount of variation caused in a dependent variable by exposure to an independent variable. But this technique cannot prove a hypothesis to be true, for there is always the possibility that the true causes of social change are not included in the model.

DEPENDENCY

The term *dependency* is most commonly used to describe a situation wherein one person relies upon another for help, guidance, reassurance, protection, or emotional support. However, it is also possible for an individual to be dependent upon a substance rather than a person, as in chemical dependency. Other uses of the dependency concept in social science include economic dependency (i.e., one person’s reliance on another for financial support), and functional dependency (i.e., one person’s reliance on another for physical help, or for assistance in carrying out activities of daily living).

PERSONALITY TRAITS

Although different forms of dependency are of interest to economists, sociologists, gerontologists, and others, the dependency concept is most widely used in psychology. In addition to studying chemical dependency, psychologists have devoted considerable effort to understanding the causes and consequences of dependent personality traits. In this context, researchers distinguish interpersonal dependency from pathological dependency. Interpersonal dependency describes the normal help- and reassurance-seeking that most people exhibit in everyday life; individuals with high levels of interpersonal dependency show above-average rates of help- and reassurance-seeking. Pathological dependency—which when pronounced may warrant a diagnosis of dependent personality disorder—describes an extreme form of maladaptive, inflexible dependency characterized by fear of abandonment, feelings of powerlessness and ineffectiveness, and an inability to initiate tasks or make decisions without excessive advice and reassurance from others.

High levels of interpersonal dependency are associated with a predictable array of personality traits including conformity, compliance, suggestibility, introversion, insecurity, interpersonal yielding, and low self-esteem. Among the psychological disorders most commonly found in people with pathological dependency are depression, anxiety disorders (especially social phobia and agoraphobia), and eating disorders (i.e., anorexia and bulimia). Contrary to clinical lore, high levels of pathological dependency do not predispose people to chemical dependency. In fact, studies show that in most cases increases in dependent attitudes and behaviors follow, rather than precede, the onset of addiction.

Although about 30 percent of the variance in level of both interpersonal and pathological dependency is attributable to genetic factors (presumably inherited differences in infantile temperament), parenting plays a key role in the etiology of dependent personality traits. Two parenting styles are particularly important in this context. First, overprotective parenting is associated with high levels of dependency in offspring. In addition, authoritarian (i.e., rigid, inflexible) parenting leads to high levels of dependency later in life. Both parenting styles lead to increased dependency because overprotective and authoritarian parents inadvertently teach children to look to others for guidance, protection, and support, and accede to others’ demands without question.

Most psychologists conceptualize dependent personality traits as consisting of four major components: (1) cognitive (a perception of oneself as vulnerable and weak, coupled with the belief that other people are comparatively powerful and potent); (2) motivational (a strong desire to obtain and maintain nurturant, supportive rela-
tionships); (3) emotional (fear of abandonment and fear of negative evaluation by others); and (4) behavioral (use of various self-presentation strategies to strengthen interpersonal ties). Among the self-presentation strategies most commonly associated with dependency in adults are supplication (appearing weak to elicit caregiving responses from others), and ingratiation (performing favors to create a sense of indebtedness in others). However, when these more common interpersonal strategies prove ineffective, people with pathological dependency may resort to intimidation (e.g., breakdown threats, suicide gestures) in a desperate attempt to preclude abandonment.

Although the cognitive, motivational, emotional, and behavioral features of dependency are relatively stable over time and across situation, dependency is expressed in different ways at different ages. During childhood dependency needs are directed primarily toward parents and other authority figures (e.g., teachers, coaches), but in adolescence the target of dependency strivings often shifts to the peer group. During early and middle adulthood dependency strivings are expressed most commonly around romantic partners, friends, supervisors, and colleagues at work; later in life dependency needs tend to be directed toward caregivers as well as romantic partners and peers.

CONSEQUENCES, FACTORS

Despite the fact that dependency in adults is usually regarded as a sign of weakness, dysfunction, and immaturity, dependent personality traits are actually associated with both positive and negative consequences. On the negative side, dependent people tend to overuse health and mental health services, react strongly to even minor relationship conflict, and have difficulty assuming leadership positions. On the positive side, however, dependent people delay less long than nondependent people in seeking medical help following symptom onset, are skilled at deciphering subtle verbal and nonverbal cues, and perform well in collaborative tasks when provided with adequate structure.

On questionnaire and interview measures of interpersonal and pathological dependency women tend to obtain higher scores than men do. These gender differences in self-reported dependency begin by mid-childhood and persist through late adulthood. A very different pattern is obtained when projective measures (e.g., the Rorschach Inkblot Test) are used to assess dependency: When these more subtle measures are administered women and men obtain comparable dependency scores. It appears that women and men have similar levels of underlying dependency needs (as reflected in comparable scores on projective dependency tests). However, men are less willing than women to acknowledge these needs in interviews and on questionnaires.

Like gender, culture affects the expression of interpersonal dependency, with individuals raised in sociocentric cultures (i.e., cultures that emphasize interrelatedness over individual achievement) showing higher self-reported dependency than individuals raised in individualistic cultures (which typically emphasize individuation and achievement over interpersonal connectedness). Studies further suggest that when individuals immigrate and gradually become acculturated to a new society, dependency levels tend to increase or decrease in accordance with the norms and values of that society.

DEPENDENCY THEORY

In the early 1950s, a group of economists stationed at the United Nations Economic Commission for Latin America (ECLA) in Santiago, Chile, launched a rigorous research program around one pressing question: What accounts for the growing divergence in living standards and gross domestic product (GDP) between the wealthy countries of the industrialized North and the poorer developing countries of the South? In 1850, for example, Argentina was among the richest nations of the world and GDP per capita in Latin America was $245, compared to $239 in North America. A century later, Argentina was mired in debt and poverty, and GDP per capita in Canada and the United States had quickly outpaced that of Latin America as both had firmly joined the ranks of the developed-country bloc.

According to neoclassical economic theory, strong trade and investment linkages between North and South should lead to a positive-sum outcome for all participants. However, by the 1950s it was difficult to ignore the widening global cleavages between North and South, as well as the growing gap between rich and poor within the
developing countries. This latter trend, characterized by an uneasy coexistence between a modern urbanized sector of the economy with strong global ties and a largely rural traditional sector where production modes sorely lagged, was increasingly referred to as dualism. Both dualism and the North-South divide became the focus of conceptual debates and practical policy prescriptions for a new generation of dependency school theorists that emerged during the 1960s and 1970s.

At heart, most dependency theorists saw the problem of underdevelopment as the inherently exploitative and contradictory nature of the capitalist system, which pitted capitalists and workers against each other as both sought to maximize their respective economic well-being. The North, with its capital abundance and accumulation of wealth, was the oppressor, while the South, with its ready supply of cheap labor and vastly rich land and natural resources, was the oppressed. It was the external sector that perpetuated underdevelopment, as well as the various private (multinational corporations) and public entities (the World Bank, the International Monetary Fund, and industrial-bloc governments) that represented it.

Whereas the earlier diagnoses of ECLA had generated proposals for restructuring the developing world’s economic relationship with the northern industrial bloc, the dependency school advocated assertive state intervention to promote the economic and political independence of the developing world vis-à-vis the North. Along with endorsing ambitious programs of import-substitution industrialization, the dependency school expanded the ECLA critique to include the urgent need for the underdeveloped South to overcome its dependence on the developed North through any variety of means, state intervention being one of these.

A RICH DEBATE
An initial wave of dependency thinking was triggered by the work of the Argentine economist Raúl Prebisch (1901–1986), director of his country’s first central bank from 1935 to 1943 and subsequently the executive secretary of ECLA between 1949 and 1963. In Prebisch’s classic 1949 treatise, *The Economic Development of Latin America and Its Principal Problems*, he introduced the idea of an industrial, hegemonic center and an agrarian, dependent periphery as a framework for understanding the emerging international division of labor between North and South. Prebisch argued that the wealth of poor nations tended to decrease when that of rich nations increased due to an unequal exchange of industrial versus agricultural goods in the North-South trading relationship. For the early structuralists, industrialization was considered a necessary step toward rectifying this pattern of unequal exchange and thus the most important objective in a development program.

From here, dependency theory quickly divided into diverse strands. Most notably, André Gunder Frank (1929–2005) adapted it to Marxism, as did Paul Baran (1910–1964), arguing that imperialism and the colonial legacy had left Asia, Africa, and Latin America in a highly disadvantageous position. Like Karl Marx (1818–1883), these theorists argued that economics was the main determinant of politics, and that social class should be the prime unit of analysis. Frank identified a “comprador class” of local southern elites whose interests and profits from this system of exploitation had become closely intertwined with their counterparts in the developed or metropolitan countries. For both Baran and Frank, this third world bourgeoisie was parasitic in nature, leaving it to workers and peasants to break with imperialism and move a given nation toward progress. While acknowledging the debilitating nature of these dual economies, others such as Ernesto Laclau criticized the Marxists for overlooking important distinctions between capitalist and precapitalist modes of production in the South. Given the tenacity of the latter, Laclau argued, it made no sense for dependency analysts to focus solely on capitalist modes of production as the linchpin for change.

Another key debate within the dependency school concerned the weight that should be given to domestic or international factors. In contrast to the hard-line Marxian viewpoint, which held that southern development could only be grasped by placing this process within its proper global historical context, Fernando Henrique Cardoso and Enzo Faletto (1935–2003) argued that it is the internal dynamics of the nation-state and not its structural location in the international division of labor that determines a country’s fate. Cardoso and Faletto emphasized that external factors had different impacts across the developing world due to the diverse internal conditions (history, factors of endowment, social structures) inherent in each country. In contrast to Frank or Baran, they regarded the national bourgeoisie within dependent peripheral societies as a potentially powerful force for social change and economic progress.

There were other points of consensus among dependency theorists. First, most saw the problem of underdevelopment as deeply rooted in the colonial experience and subsequently perpetuated by a sophisticated set of transnational class linkages composed of political and military elites, powerful economic interests, multinational corporations, and multilateral institutions like the International Monetary Fund. Second, and in light of this cumulative historical legacy, dependency theorists saw the world economy as a functionally integrated whole in which a huge underdeveloped periphery of poor states,
and a semiperipheral group of partially industrialized developing countries, are dominated by the industrial-bloc countries that form the core. Third, the nature of economic interaction between these segmented markets is such that the peripheral and semiperipheral countries are stuck in a zero-sum game characterized by diminishing returns from trade and investment with the North.

Dependency theorists were most likely to part ways when it came to the practical political and economic policy prescriptions that flowed from this worldview. One main difference arose between those advocating that the development of the periphery could still be achieved by working within the confines of the capitalist system and those who saw the need for a complete rupture with the advanced capitalist powers and the pursuit of a state-planned socialist model. The former stance embraced a more dynamic and evolutionary view of economic development and the possibilities to achieve upward mobility within the capitalist framework; the latter saw the future of the underdeveloped periphery as locked into a static world economic system that had determined its fate since the sixteenth century and could only be rectified via outright revolution and the installation of a socialist economy.

EMPIRICAL CHALLENGES

Even as dependency theory flourished in Africa, Asia, and Latin America, the empirical validity for many of its presumptions was shaky at best. The more revolutionary brand of dependency thinking had been fueled by evidence of the region’s robust growth during the first and second world wars, as demand boomed for the region’s commodities. Although a unique set of historical circumstances, this wartime boom prompted some to call for a complete de-linking of North and South, the nationalization of major industries, and levels of protectionism akin to autarky. Chile and Peru proceeded along such lines in the early 1970s, but with fairly dismal results.

State planners and economic policymakers in Argentina, Brazil, and Mexico also subscribed to dependency thinking, but chose to work within the capitalist system. It was the track record in such countries that informed some of the main empirical hypotheses that underpinned the dependency model, for example the Prebisch-Singer hypothesis about the secular deterioration of the terms of trade and the Lewis-Nurkse hypothesis. These hypotheses refer to an international pattern of specialization that has the northern countries exporting manufactures among themselves while the southern countries send their primary products to the North, and thus suggest that a balanced growth strategy would be the ideal strategy for less-developed countries.

The dependency era was replete with ambitious state-led policies geared toward industrial modernization and the full exploitation of those endogenous endowment factors (land, labor, and rich natural resources) with which the developing countries had been blessed. Yet, by the end of this period, the international division of labor between North and South remained basically the same, as did the pattern of “unequal exchange” that that ECLA and dependency theorists alike had originally decried. That is, the South was still largely dependent on the import of increasingly expensive manufactured and technology-intensive goods from the North and the export of primary commodities plagued by volatile price trends in return.

Perhaps the biggest empirical challenge to dependency theory was the takeoff of the newly industrializing countries of East Asia in the 1970s. While Latin America seemed to be running in place with rising inflation, poverty, and debt, countries like Japan, Taiwan, and South Korea were proving that the seemingly hierarchical structure of the world economy was not structurally determined. Under a more pragmatic set of economic policies that combined state and market approaches, this smaller and much less-endowed group of Asian countries showed that it was possible to produce high growth with better income distribution and to do so by integrating more strategically into international markets for trade and investment. Strong leadership and sound economic institutions could, in fact, mitigate the external challenges inherent in the North-South divide.

A LASTING LEGACY

While few of the dependency school’s theoretical assertions have stood the test of time, this perspective continues to offer a powerful description of the political and economic plight of the majority of countries that remain on the periphery of the world economy. A full understanding of the causal mechanisms and policy solutions for remediying underdevelopment may still be a long way off; however, the dependency school’s specification of concrete problems like dualism, inequality, diminishing returns to trade, and the North-South divide have enriched debates about development and helped them to move forward.

DEPOPULATION

Depopulation, or population decline, has become an especially relevant topic given that depopulation is projected to occur in most countries of the world during the twenty-first century. Despite the vast amount of attention paid to the phenomenon of overpopulation since the late 1960s (see Ehrlich 1968; Meadows, Randers, and Meadows 2004; Friedman 2005), declines in population are expected to occur in around fifty or more countries by the year 2050, according to the Population Reference Bureau, and in even more countries thereafter. Although the overall population of the world is projected to continue to grow, reaching around 9.1 billion by 2050 (according to the United Nation’s medium-variant projection), a slowing of the rate of population growth is already under way, and a decline in the size of the population of the world could begin as early the middle of the twenty-first century. The region of the world most significantly impacted by depopulation is Europe. Between 2000 and 2005 at least sixteen countries in Europe had already experienced a decline in population. The largest net loss in population has occurred in Russia, with a decline of almost 3.4 million persons in the five years between 2000 and 2005.

For most of the world’s countries, the reason for the net loss in population is sustained low fertility. In order for a population to be stationary (neither grow nor decline), the total fertility rates (TFRs) need to be at replacement level (2.1 children per woman) for an extended period of time, and the cohorts in the childbearing ages cannot be larger than those in other age groups. If there are large numbers of people in the parental ages, replacement level fertility alone will not result in depopulation. This is due to the phenomenon of what demographers refer to as “population momentum,” which is the lag between the decline in total fertility rates and the decline in crude birth rates. This occurs when there are large numbers of women still in their childbearing years because of past high fertility. The United Nations reports that in the 2000–2005 period there were sixty-five countries with fertility rates below replacement levels. Fifteen of these had rates that were at extremely low levels (a TFR below 1.3). In 2006 the Population Reference Bureau reported that as many as seventy-three countries were experiencing total fertility rates below the replacement level (Population Reference Bureau 2006).

Many countries with relatively high TFRs experienced declines in their fertility in the late twentieth century. For example, the United Nations reports that of the thirty-five countries with a TFR of five or higher, twenty-two experienced declines in fertility between 1990 and 2005. These rates of fertility, which are lower than they were previously, coupled with low rates of mortality and immigration are responsible for population declines in the majority of countries projected to lose population. For a few countries, population decline is expected to occur even though their fertility rate is above replacement level. These countries, namely, Botswana, Lesotho, and Swaziland, are significantly impacted by the HIV/AIDS epidemic, leading to a net loss in population.

The depopulation of most of the countries in the developed world has significant economic impacts and implications. Major impacts will most likely be felt through population aging. As fertility declines, birth cohorts become progressively smaller. These smaller birth cohorts, coupled with increases in life expectancy, lead to an increasingly larger proportion of the population over the age of sixty-five and a smaller proportion of the population in the working age range. The United Nations reports that the period between 2005 and 2050 will see a doubling of the old-age dependency ratio (the ratio of the population aged 65 and over to the population aged 15 to 64, times 100) in developed countries, with this ratio growing from 22.6 to 44.4 (United Nations 2005). For many countries, health care and pension programs are ill-equipped to handle large increases in the numbers of elderly persons, who themselves will live longer than their predecessors.

The long-term effects of depopulation have prompted some countries to enact policies to encourage increases in fertility. These include financial remittances for each child born, liberal parental leave policies, and guaranteed child care and schooling for children. According to Michael Balter, writing in 2006, one of the most expensive and generous fertility policies has been enacted in Australia, where remittances per child have exceeded US$3,000. However, the effectiveness of these fertility incentives is hotly debated. Some argue that incentives are beneficial in easing the financial burdens caused by additional children, making families more willing to increase their childbearing. Others emphasize that

Carol Wise
any increases due to these policies will be small. While financial resources may make it easier for families to pay for the children they already want to have, they are unlikely to raise fertility to the level necessary to stave off population decline.

As an alternative to policies that encourage fertility increases, some demographers suggest that imbalances in population age structure can be corrected through increases in immigration. Ben Wattenberg notes in Feuer: How the New Demography of Depopulation Will Shape Our Future (2004) that since most developing countries are still experiencing high birthrates and population growth, immigration originating from these countries can supplement small working age cohorts in other countries. While international migration may be beneficial in the redistribution of national populations, immigration policies encouraging immigration from developing countries remain the least favored policies of countries experiencing population declines.

(1772–1823), who followed a classical theory of value. In contrast, Thomas Malthus (1766–1834) rejected Say’s analysis, and, in modern terms, argued that either excessive investment due to overoptimistic expectations, or hoarding, could lead to a general slump.

The most systematic nineteenth-century argument for the possibility of a general slump was given by Karl Marx (1818–1883), who divided demand into two “circuits”: the circuit of commodities $C-M-C'$ and the circuit of capital $M-C-M^+$. In the former, Say’s law in general applied; but in the latter, the capitalist’s aim “is not to equalize his supply and demand, but to make the inequality between them … as great as possible” (Marx 1885, pp. 120–121). Since aggregate demand was the sum of the two circuits, it was entirely possible for a “general glut”—or depression—to occur, if capitalist expectations of profit were depressed.

During the Great Depression itself, Keynes put forward an argument similar to Marx’s (and in a 1933 draft of his 1936 General Theory, Keynes cited Marx directly [Dillard 1984, p. 424]). Dividing effective demand into consumption demand $D_1$ and investment demand $D_2$, he argued that the sum could be insufficient to employ “the supply of labour potentially available at the existing real wage” (Keynes 1936, p. 30).

Irving Fisher (1867–1947) introduced a financial interpretation of the tendency to depression in 1933. Though Fisher had earlier developed the equilibrium model of finance, the rejection of equilibrium analysis was pivotal to his “debt deflation theory of great depressions.” It was, he argued, as absurd to assume that key economic variables were always at their equilibrium values as it was “to assume that the Atlantic Ocean can ever be without a wave” (Fisher 1933, p. 339).
Fisher argued that the Great Depression was caused by the confluence of two disequilibria: “over-indebtedness to start with and deflation following soon after” (Fisher 1933, p. 341). Excessive debt forced businesses to liquidate stock at distressed prices, leading to a fall in the price level that actually reduced the capacity to repay debt. This caused a “chain reaction” of further disturbances, including a decline in bank deposits, a fall in the velocity of circulation, unemployment, increased pessimism, an evaporation of investment, and “complicated disturbances in the rates of interest, in particular, a fall in the nominal, or money, rates and a rise in the real, or commodity, rates of interest” (Fisher 1933, p. 342).

The end product was Fisher’s paradox that “the more the debtors pay, the more they owe” (Fisher 1933, p. 344): the real debt burden rose because of deflation, even though nominal debt had been reduced by debt repayment. Fisher asserted that private debt fell by 20 percent between 1929 and 1933, but real debt rose 40 percent because of the impact of four years of steeply falling prices. He argued that the only policy that could engineer an escape from a depression was reflation, and for that reason he strongly supported Franklin D. Roosevelt’s New Deal.

The position that capitalism was innately stable, and that the Great Depression had been caused by government policy, was first put by Milton Friedman (1912–2006) and Anna Jacobson Schwartz. They claimed that the depression occurred because of deflationary policies pursued by the Federal Reserve that reduced the stock of money, and asserted that “the Federal Reserve at all times had power to prevent the decline in the money stock or to increase it to any desired degree, by providing enough high-powered money to satisfy the banks’ desire for liquidity” (Friedman and Schwartz 1963a, p. 52).

Today, neoclassical analysis of depressions is dominated by real business cycle theory, which argues that any economic outcome is the result of the actions of rational agents in a stochastically uncertain environment. In this view, the Great Depression was either the result of optimal responses by rational agents to less-than-optimal government policies, or it was the product of a monetary or productivity shock (Prescott 1999). However, since real business cycle models presume that a market economy rapidly returns to equilibrium after a shock, the slow speed of recovery from the Great Depression needs an explanation. Most theorists argue that the downward inflexibility of money wages, combined with deflation, kept real wages above equilibrium for a substantial period.

The modern representative of the “innate tendency to depression” argument is the financial instability hypothesis (FIH) developed by Hyman Minsky (1919–1996). Fisher’s debt-deflation hypothesis is one of its two pillars, the other being Joseph Schumpeter’s (1883–1950) vision of capitalism as innately cyclical. The FIH argues that capitalist economies have a cyclical tendency to accumulate excessive debt, and depressions are a runaway process in which interest on existing debt overwhelms the economy’s capacity to service debt.

There are thus two modern perspectives on the causes of depressions—neoclassical real business theory and the FIH—with fundamentally opposed analyses and policy prescriptions. Deciding which is right is therefore important, given that what one says will cure a depression, the other says will make it worse.

An essential premise of the neoclassical perspective is that the government controls the money supply. This not only makes the government a cause of depressions, but also gives it an easy means to overcome one. In the words of Federal Reserve Chairman Ben Bernanke, “If we do fall into deflation, however, we can take comfort that … sufficient injections of money will ultimately always reverse a deflation” (Bernanke 2002).

The FIH, on the other hand, argues that money is largely endogenous, so that attempting to increase liquidity by “the logic of the printing press” (Bernanke 2002) is, in effect, “pushing on a string.” Strictly, monetary attempts to reflate out of a depression will, in this theory’s view, probably fail. However, this model concurs that the government should attempt to maintain liquidity during a depression.

Since the neoclassical model sees sticky wages as part of the problem, its solution is to remove labor market institutions that prevent wages from falling sufficiently quickly. The debt-deflation model puts the contrary position that falling money wages will only lead to further falls in prices, which will exacerbate the problem of deflation. It recommends the opposite policy: that money wages should be increased to cause inflation and thus reduce the real debt burden.

Though neoclassical real business cycle theory dominates academic economics today, many papers in this tradition are candid about the empirical weakness of their models, with implausibly large productivity shocks or monetary reaction functions being required to fit the data. The Japanese depression of 1990 until 2005 also challenges the belief that deflation can be easily reversed by increasing base money. Very large changes in M1—at rates of up to 32 percent per annum—had little discernible impact on either the overall money supply (M2) or price levels (see Figure 2).

On this measure at least, the evidence appears to support the FIH perspective. However, given the dominant position of neoclassical analysis within economics, there is little doubt that, should a depression recur, the policies followed in the first instance will be neoclassical in nature.

Say, Jean-Baptiste. [1821] 1967. *Letters to Mr. Malthus on Several Subjects of Political Economy and on the Cause of the
DEPRESSION, PSYCHOLOGICAL

Depression is a common psychiatric disorder that places a great burden on society. Major depressive disorder (MDD) is defined by the American Psychiatric Association as characterized by dysphoric mood and/or loss of interest or pleasure in all or nearly all activities, plus at least four other symptoms (e.g., sleep problems, appetite disturbance, fatigue, psychomotor agitation or retardation, feelings of worthlessness or guilt, difficulty concentrat ing or making decisions, recurrent thoughts of death or suicide), that occur during most of the day, nearly every day, for at least two weeks and with significant impairment in social or occupational functioning. Dysthymic disorder (DD) lasts at least two years in adults (and at least one year in children and adolescents). It is defined by similar, although fewer, symptoms (i.e., depressed mood and at least two of the following: appetite problems, sleep disturbance, fatigue, low self-esteem, concentration difficulties, hopelessness).

Subtypes of MDD include atypical depression (characterized by weight gain and an increase in sleep and appetite), melancholic depression (characterized by pervasive loss of interest or pleasure, or lack of mood reactivity, and at least three of the following: distinct quality of mood, mood worse in the morning, terminal insomnia, psychomotor disturbance, significant appetite decrease or weight loss, excessive guilt) and cyclical depression (e.g., seasonal affective disorder).

Bipolar disorder is characterized by dramatic swings from depressive to manic episodes (e.g., elevated, expansive, or irritable mood) that last at least one week (four days for hypomania), or any duration if hospitalized, during which individuals experience at least three of the following symptoms (four, if mood is only irritable): inflated self-esteem, decreased need for sleep, pressured speech, racing thoughts, distractibility, increased goal-directed activity, or risky behaviors. These symptoms occur most of the day, nearly every day, with clinically significant impairment.

Depression also falls on a continuum of severity from sad mood to diagnosed depressive disorders. The subjective state of sadness by itself is not necessarily pathological, but when it occurs simultaneously with other symptoms it is referred to as a symptom complex or syndrome. A clinical syndrome is considered a distinct disorder when it has a specific course, outcome, etiology, and treatment response.

EPIDEMIOLOGY

In the United States, lifetime prevalence rates are 20.8 percent for any mood disorder; 16.6 percent for MDD; 2.5 percent for DD; and 3.9 percent for Bipolar. Lifetime prevalence rates of MDD differ by gender, with 21.3 percent reported for women and 12.7 percent for men; by age, with 0.3–2.5 percent reported for children, 15–20 percent for adolescents, and 10.6 percent for older adults; and by nation, with 1.5 percent reported in Nagasaki, Japan, and 27.3 percent in Santiago, Chile. In a given year in the United States, the incidence of MDD is 3.0 per 1,000 and the incidence of any mood disorder is 9.5 percent.

Depression is recurrent and often chronic. Median MDD durations range from 19 to 22 weeks in adults across multiple episodes, and mean durations range from 26 to 36 weeks in children and adolescents. Remission is defined as no longer meeting full criteria for a depressive episode. If another "episode" develops before two months pass with only minimal symptoms, it is considered a relapse (for predictors of relapse see Keller et al. 1983); if more than two months have elapsed, it is considered a recurrence (for predictors of recurrence see Keller and Bolland 1998).

ETIOLOGY

The etiology of depression involves the complex interplay of genetic, biological, personality, cognitive, interpersonal, and environmental factors. Kenneth Kendler's developmental model of MDD in women has identified an internalizing pathway (including neuroticism and early-onset anxiety disorders), an externalizing pathway (focusing on the role of conduct disorder and substance misuse), and an adversity pathway (e.g., disturbed family environment, childhood sexual abuse, parental loss), all of which might be anchored in genetic risk.

There is extensive evidence showing a link between stressful life events and the onset and maintenance of depression in both children and adults, although there is considerable variability in how different individuals respond to the same stressful event. Diathesis-stress theories focus on interactions among individual vulnerabilities and life stressors. Stress "activates a diathesis, transforming the potential of predisposition into the presence of psychopathology" (Monroe and Simons 1991, p. 406). A
A wide range of genetic and psychosocial vulnerability factors have been identified with regard to depression. Avshalom Caspi and colleagues (2003), and others, have shown one such gene-environment interaction: a functional polymorphism in the promoter region of the serotonin transporter gene that moderates the influence of stressful life events on depression.

It is not clear how much variance in depression can be attributed to genetic factors. Twin studies conducted by Patrick Sullivan, Michael Neale, and Kenneth Kendler in 2000 found that 31 to 42 percent of the variance in liability to depression was explained by additive genetic effects, 58 to 67 percent by individual specific environmental effects, and a negligible 0 to 5 percent by shared environmental effects. In contrast, adoption studies have typically reported negligible genetic effects and evidence of small but significant shared environment effects.

A number of biological processes have been implicated in depressive disorders. As outlined by Michael Thase, Ripu Jindal, and Robert Howland in 2002, depressed individuals show neuroendocrine dysregulation in the form of abnormal hypothalamic-pituitary-adrenal (HPA) axis response to stress, hyposecretion of growth hormone (GH) in response to pharmacologic challenge, and neurochemical dysregulation, particularly in the serotonergic and dopaminergic systems. Studies have also found that abnormal functioning of the prefrontal cortex-limbic-striatal regions, reduced prefrontal volume, and hippocampal abnormalities are associated with depression (see Davidson et al. 2002).

Personality, defined as an individual’s characteristic pattern of thinking, feeling, behaving, and relating to others, has long been linked with depression, and it may moderate the effect of stress on depression. The personality trait of negative emotionality (NE), defined as the propensity to experience negative emotions (e.g., anxiety, fear, sadness, anger), has been particularly associated with depression. Related constructs include negative affectivity and neuroticism.

Cognitive models of depression assert that individuals who have negative beliefs about themselves, the world, and their future, and who have a tendency to make global, stable, and internal attributions for negative events, are more likely to become depressed when confronted with stressors than are individuals without such negative beliefs. Evidence consistent with the cognitive-stress interaction has not been found prior to late childhood or early adolescence around the time when children are developing abstract reasoning and formal operational thought.

Interpersonal vulnerability to depression is characterized by impaired social skills, interpersonal dependency, and social inhibition. The relation between interpersonal difficulties and depression is most likely reciprocal and transactional. Some depressed individuals engage in excessive reassurance-seeking from others concerning their worth and loveliness. This behavior may provoke frustration and irritation in others, thereby eroding social support and generating increased stress. The centrality of social ties in relation to depression has received considerable empirical support, and such ties may play a role in gender differences in the rates of depression that begin to emerge during adolescence.

**INTERVENTION**

Pharmacotherapy is the most common approach to the treatment of depressive disorders. Meta-analyses of randomized controlled studies indicate that serotonin and noradrenaline re-uptake inhibitors (SNRIs) demonstrate superior efficacy over selective serotonin re-uptake inhibitors (SSRIs), which in turn present with different side-effect profiles and superior general tolerability compared to tricyclic antidepressants (TCAs). In depressed youth, fluoxetine, an SSRI, has been found to perform significantly better than a placebo. Patients with bipolar disorder are frequently treated with mood stabilizers such as lithium, valproate (Depakote), or lamotrigine (Lamictal).

Cognitive-behavioral therapy (CBT) is one of the most effective psychosocial treatments for depression. In CBT, individuals are taught to modify negative thought patterns, realistically evaluate the accuracy of their beliefs, and develop problem-solving and coping skills (see Beck et al. 1979). In a 1999 mega-analysis of data from several treatment studies, Robert DeRubeis and colleagues found that cognitive therapy was as effective as medications in the treatment of more severely depressed adult patients. Although medications can be quite effective in reducing acute symptoms of depression, they do not reduce the risk of subsequent depressive episodes once their use is discontinued. In contrast, cognitive therapy has been shown to have an enduring effect following successful treatment. In adolescents, a large clinical trial yielded favorable results for CBT compared to supportive or family therapy (see Brent et al. 1997). The Treatment for Adolescents with Depression Study (TADS 2004) found that at the 12-week assessment CBT alone did not fare as well as medications (fluoxetine) alone or medications in combination with CBT. However, the difference between CBT and medications alone was no longer present by the 18-week assessment.

Interpersonal psychotherapy (IPT) for depression addresses problems associated with role transitions, grief, interpersonal deficits, and interpersonal disputes. In studies with depressed adults, IPT has performed better than treatment as usually provided in the clinic, or placebo, although not better than cognitive therapy or tricyclic
antidepressant medications with and without IPT (see Shulberg et al. 1996). An adaptation of IPT for use with depressed adolescents has been found to be efficacious (see Mufson et al. 1999).

Studies aimed at preventing depression have shown positive, albeit modest, effects. Universal prevention programs, which target all members of a population, have not been found to be as effective as selective programs targeting individuals at risk or indicated programs targeting individuals who are already showing symptoms but do not have the full disorder. Although evidence is growing that depression can be prevented, the effects have tended to be relatively short-lived. Future research needs to develop and test interventions that have more enduring preventive effects. It is also important to identify who is most likely to benefit from which type of intervention, as well as the mechanisms through which such programs work.

DEREGULATION

Throughout most of the twentieth century, advanced industrialized nations embraced a notion of the state as being an agency of the “common good,” as overarching and mediating the sectional and competing interests of civil society. The material underpinning of this discourse was the failure of private corporations to maintain an adequate provision of public goods through the market as well as the general belief that firms, if left unfettered, might conduct their business at the expense of the “public interest.” In order to protect citizens and consumers, therefore, the state undertook the direct administration and provision of certain public goods—such as defense, the rule of law, various aspects of education, health, water supply, and electricity—through the planning of investment and the allocation of resources. Markets for private goods, in turn, were subjected to regulations with regard to product quality, safety, and other attributes.

During the last two decades of the century, however, it became clear that the state was embedded in a global capitalist system, and that its autonomy to engage in regulation and provision had become constrained by the logic and dynamics of that system. State regulation and planning ultimately resulted in an increasingly severe fiscal crisis, with rising public expenditures and debts, persistently high levels of inflation, and weak balances of payment. Governments were forced to reassess their approach, and they started to embrace the emerging doctrine of neoliberal economic and social theory.

NEOLIBERAL THEORY

Neoliberal economics is premised upon a conception of the individual as a rational utility-maximizing consumer. Neoliberal proponents argue that when consumers spontaneously and impersonally interact in the market, the result is both individual liberty and economic efficiency. The market, which has no ends or purposes, allows individuals to incorporate their consumption into a personal
plan that spontaneously produces the optimum allocation of social resources.

The resultant neoliberal restructuring of the state was an attempt to realign both the state and international capital by depoliticizing decisions about the allocation and provision of services. This has involved the privatization of some sectors of the economy, a redefinition of the concept of public services, and the gradual removal of restrictions on businesses. The stated rationale was that fewer regulations would lead to greater competitiveness, and therefore to higher productivity and efficiency, and to lower prices for consumers.

MARKET FAILURES AND RE-REGULATION

However, various high-profile failures of deregulation—such as the savings and loans crisis in the United States in the 1980s and the California electricity crisis at the end of the 1990s—brought home the point that consumers and citizens require protection from various forms of market failure, such as:

1. negative externalities, which occur when the socially optimal output diverges from the private optimum, as is the case with environmental pollution;
2. monopolies, which occur when an entity's market power prevents competition, and therefore allows higher prices to be charged at lower output than is feasible in a competitive market, producing a net economic welfare loss, allocative inefficiency, and a Pareto suboptimal equilibrium;
3. instances in which some public goods may not be provided by the free market at all because of their characteristics of nonexcludability and nonrivalry;
4. inequality, which occurs when differences in income and wealth restrict some members of society from accessing vital goods and services.

Strengthened regimes of re-regulation were developed as a result of these concerns. If regulation can reduce prices below monopoly levels and provide a remedy for other market failures without compromising new entry, competition, choice, innovation, and other long-term attributes of a competitive market, then the case for it is compelling, at least during the transition to a competitive market. Examples include pollution taxes to correct for externalities; taxation of monopoly profits (the “windfall tax”); regulation of oligopolies and cartel behavior; continued and direct provision of some public goods (e.g., defense; law and order); subsidies; product and safety regulations; the specification of output levels and quality; and price controls.

CRITICISMS

Regulation creates questions about the extent to which it actually works in the public interest. The specification of what the optimum regulatory solution should be is insufficient if not supplemented by a theory of the behavioral motivations underlying both regulators and those regulated. The “capture model,” for example, argues that actors’ respective self-interests will produce a regulation policy that maximizes their joint interest in stable and predictable outcomes, but that may also be skewed toward the monopoly solution that regulatory policy is seeking to prevent in the first place.

In addition, regulators may not have sufficiently precise information about the cost structure and consumer responsiveness to price changes to be able to properly set output and prices in a given industry. Regulators are therefore dependent upon those regulated to provide them with basic information, a situation that may create opportunistic behavior in the resultant interaction process. The challenge, then, is well known from other areas of the social sciences and is generally referred to as the principal-agent problem, namely how best to design a system of contracts that motivates the regulatees to act in the interest of the regulators—within the constraints of imprecision, lack of observability, bounded rationality, and asymmetric strategic moves.

DERRIDA, JACQUES 1931–2004

Jacques Derrida was one of the most original and influential French philosophers in the contemporary world. He was born in Algeria on July 15, 1931, to a Sephardic Jewish family. He moved to France in 1949 and studied in Paris at the École Normale Supérieure, where he wrote his dissertation on Edmund Husserl's genetic phenomenology (Le Problème de la genèse dans la philosophie de Husserl...
Derrida, Jacques

[The Problem of Genesis in Husserl’s Philosophy], 1953–1954). In the 1960s Derrida published major works concerned with the limitations of phenomenological and structuralist thought in the human sciences. Prior to his death, he was the director of studies at the École des Hautes Études en Sciences Socialies in Paris and professor of humanities at the University of California, Irvine. Derrida died on October 8, 2004.

Derrida is today universally recognized as the leading figure in the field of poststructuralist thought designated by the term deconstruction. He is typically referred to as the most prominent critic of Western metaphysics (understood as a universal discourse that is foundational, subject-oriented, and logocentric); he is also frequently described as an antihumanist, a postphenomenologist, and the founding father of the discipline of grammatology. His early writings are best represented by three key texts: La Voix et le phénomène (Speech and Phenomena), De la Grammatologie (Of Grammatology), and L’Écriture et la différence (Writing and Difference), all published in 1967. These works were the first to circulate the poststructuralist themes of the role of différence, textuality, and writing in all systems of meaning (and thereby to set into play wider currents of research in disciplines concerned with the dynamic characteristics of texts, writing, and cultural dissemination).

Derrida is particularly noted for questioning the unity, direction, and stability of traditional philosophical discourse. Yet thematically his major writings have all been concerned to advance careful readings and interpretations of the texts of major figures in both ancient and modern philosophy, including Plato (427–347 BCE), Immanuel Kant (1724–1804), Jean-Jacques Rousseau (1712–1778), G. W. F. Hegel (1770–1831), Edmund Husserl (1859–1938), Martin Heidegger (1889–1976), and Sigmund Freud (1856–1939). These writings are supplemented by analyses of such “nonphilosophers” as Samuel Beckett (1906–1989), Maurice Blanchot (1907–2003), George Bataille (1897–1962), and Jean Genet (1910–1986), among other important literary figures. Derrida reads all of these texts as complex intertextual “objects” saturated with indeterminate meanings, ambivalent oppositions, and “undecidable” interpretations.

For many readers in the analytic or Anglophone tradition of philosophical thought, Derrida is a subversive relativist, a nihilist word-player who has largely abandoned the pursuit of rational criticism to embrace a form of negative and playful experiment with words and their indefinite allusions and meanings. Derrida’s pantextualism was notoriously symbolized by his claim “Il n’y a pas de hors-texte,” usually translated as “There is nothing outside of the text,” but perhaps more literally expressed as “There is nothing outside of text” (a declaration that Derrida later reformulated to “Il n’y a pas de hors contexte,” or “There is nothing outside of context”). On this reading, Derrida is frequently grouped with other “enemies of reason” as an irrationalist or even a nihilist. In this interpretation, the terms deconstruction and deconstructionist have been used as derogatory expressions designed to define deconstruction as a method of literary criticism rather than serious philosophy (an approach that remains oblivious to the fact that Derrida spent a lifetime of painstaking reading and commentary with the objective of questioning and deconstructing this type of binary opposition).

Despite such one-sided interpretations, what has come to be called deconstructive studies has had a major impact upon contemporary philosophy, literary theory and criticism, sociology, educational practices, media, and cultural studies. One of the first intellectual traditions to assimilate Derrida’s work was the Yale school of literary criticism, struggling to elaborate forms of reading and interpretation richer than the available models of new criticism. In this context, we can mention the work of Paul de Man (1919–1983), Harold Bloom, Geoffrey Hartman, and J. Hillis Miller. Following Derrida’s lead, these critics have radically questioned the nature of literary “meaning,” “authorship,” and “authorial intentionality” by uncovering the metaphysical presuppositions and binary oppositions that have structured the methods of traditional textual analysis and interpretation. In generalizing deconstruction from texts narrowly conceived in literary-critical terms to the “general text” of social life, we have come to see that all theory and research in the human sciences is inextricably involved in complex questions of language and interpretation.

In his later work, Derrida turned to a range of problems linked with contemporary social and political life. His writings became increasingly preoccupied with urgent ethical and political problems of European integration, immigration and the treatment of “asylum seekers,” and questions of friendship and otherness in an increasingly borderless, cosmopolitan world order. His books Of Hospitality (2000), On Cosmopolitanism and Forgiveness (2001), and The Work of Mourning (2001) are indicative of these themes.

While Derrida’s work has profoundly changed the practice of philosophical analysis, literary theory, and other textual sciences, perhaps his most long-lasting impact lies in the turn toward ethical and political issues that has transformed the intellectual landscape of what passes for the theory and practice of the human sciences, the arts, and philosophy.

DESCRIPTIVE STATISTICS

Descriptive statistics, which are widely used in empirical research in the social sciences, summarize certain features of the data set in a study. The data set nearly always consists of lists of numbers that describe a population. Descriptive statistics are used to summarize the information in the data using simple measures. Thus, descriptive statistics can help to represent large data sets in a simple manner. However, an incautious use of descriptive statistics can lead to a distorted picture of the data by leaving out potentially important details.

THE HISTOGRAM

Descriptive statistics take as a starting point observations from a population. So suppose we have observed \( n > 1 \) draws from a population, and let \( [x_1, \ldots, x_n] \) denote these observations. These observations could, for example, be a survey of income levels in \( n \) individual households, in which case \( x_1 \) would be the income level of the first household and so forth. One way of doing this is through the distribution of the data that gives a summary of the frequency of individual observations. The distribution is calculated by grouping the raw observations into categories according to ranges of values. As a simple example, Table 1 reports the distribution of a data set of income levels for 1,654 households in the United Kingdom. The data set has been grouped into five income categories. These categories represent income in U.S. dollars within the following ranges: \( 0–$700; \ $701–$1,400; \ $1,401–$2,100; \ $2,101–$2,800; \ and \ $2,801–$3,500. The second row in Table 1 shows the number of households in each income
range. The corresponding frequencies are found by dividing each cell with the number of observations; these are given in the third row.

One can also present the frequencies as a graph. This type of graph is normally referred to as a histogram. The frequencies in Table 1 are depicted as a histogram in Figure 1.

### SUMMARY STATISTICS

An even more parsimonious representation of the data set can be done through summary statistics. The most typical ones are measures of the center and dispersion of the data. Other standard summary statistics are kurtosis and skewness.

The three most popular measures of the center of the distribution are the mean, median, and mode. The mean, or average, is calculated by adding up all the observed values and dividing by the number of observations:

$$\bar{x} = \frac{\sum_{i=1}^{n} x_i}{n}$$

The median represents the middle of the set of observations when these are ordered by value. Thus, 50 percent of the observations are smaller and 50 percent are greater than the median. Finally, the mode is calculated as the most frequently occurring value in the data set.

The dispersion of the data set tells how much the observations are spread around the central tendency. Three frequently used measures of this are the variance (and its associated standard deviation), mean deviation, and range. The variance (VAR) is calculated as the sum of squared deviations from the mean, divided by the number of observations:

$$\text{VAR} = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^2$$

The standard deviation (SD) is the square-root of the variance: \(\sqrt{\text{VAR}}\). The mean deviation (MD) measures the average absolute deviation from the mean:

$$\text{MD} = \frac{1}{n} \sum_{i=1}^{n} |x_i - \bar{x}|$$

The range is calculated as the highest minus the lowest observed value. The range is very sensitive to extremely large or extremely small values, (or outliers), and it may, therefore, not always give an accurate picture of the data.

Skewness is a measure of the degree of asymmetry of the distribution relative to the center. Roughly speaking, a distribution has positive skew if most of the observations are situated to the right of the center, and a negative skew if most of the observations are situated to the left of the center. Skewness is calculated as:

$$\text{SKEW} = \frac{m_3}{SD^3} = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^3$$

Kurtosis measures the “peakedness” of the distribution. Higher kurtosis means more of the variance is due to infrequent extreme deviations. The kurtosis is calculated as:

\[
\text{KURT} = \frac{m_4}{SD^4}, \quad m_3 = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^3

DESEGREGATION

Segregation can be both voluntary and involuntary, forced and by mutual agreement. When segregation results in exclusion from public goods, rewards, and privileges, or when segregation results in stigmas, then a violation of the basic conditions of democracy is evident. When such segregation occurs along racial lines, it becomes racial segregation. When racial segregation is operant across major social institutions, it is considered institutional racism.

Efforts in the United States since the mid-twentieth century have been aimed at reversing racial segregation. These efforts, labeled desegregation, are political processes that make use of civil protest, litigation, and economic sanctions to eliminate racial segregation. Racial segregation, both de jure and de facto, has historically served to restrict access to education and training, economic and political institutions, occupational and social mobility, religious and social institutions, and neighborhoods and transportation facilities. Within the United States, most desegregation activity has focused on educational institutions, public accommodation, and the military.

While many cite the 1954 Supreme Court decision in Brown v. Board of Education of Topeka as the beginning of desegregation, in actuality desegregation reflects a process that continues into the twenty-first century. The Brown decision, by striking down legal segregation on the basis of race in public schools, reversed the Supreme Court’s 1896 decision in Plessy v. Ferguson.

DESEGREGATION IN EDUCATIONAL INSTITUTIONS

Throughout history, one of the primary tactics of exploitative systems was control of access to education. Some of the first laws aimed at controlling Africans during the slavery era prohibited or restricted educational access. These laws, which carried harsh sanctions, denied educational access not only to slaves but to freed Africans as well. The same method was used to keep European women, Native Americans, Chinese, and others in subordinate positions. It is no wonder that one of the major features of the various civil rights movements has been directed at dismantling segregated or restricted access to educational institutions.

Although many thought the Civil War (1861–1865) and the associated constitutional amendments would resolve the issue of segregation in the United States, the Plessy v. Ferguson ruling actually mandated it. Within months after this historic ruling, seventeen southern states began to implement sets of laws—known as Jim Crow or de jure segregation—that formalized and legitimized racial segregation in most institutional spaces. Among these were laws that established “separate but equal” educational facilities. While often lacking specific legislation, the North accomplished the same effect through what has been termed de facto segregation.

The 1954 Brown v. Board of Education ruling, with its aim to end school segregation, struck at the heart of the system of racial entitlements in the United States. Nothing less than a revolution was envisioned. As pointed out by Gary Orfield and Susan Eaton (1996), integration did not represent a magical process in which simply situating whites and blacks in the same room would end centuries of discrimination. Rather, it recognized that white dominance had been engineered through exclusive control of select schools. Ending this dominance and making such schools available to all would serve to remove the racial stigma and victimization of blacks, provide black Americans access to other major institutions, and level the playing field, thereby assuring equality and freedom. The Supreme Court ruled that racially segregated schools did indeed perpetuate racial stigmas among blacks, and that such schools were therefore inherently unequal. Yet, in striking down Plessy, the Supreme Court decided ambiguously that integration should take place “with all deliberate speed.”

“All deliberate speed” has been described as simultaneously placing the country’s feet on both the accelerator and the brake. Throughout the South, a multitude of strategies were instituted to delay, divert, or otherwise circumvent the Brown ruling. In 1956 advocates of segregation were successful in convincing Virginia’s governor and state assembly to pass laws blocking the funding of school
integration. One of the most striking anti-integration efforts occurred in 1957 when Arkansas governor Orval Faubus (1910–1994) ordered the state’s national guard to block the doors to Little Rock’s Central High School, preventing nine black teenagers from entering. Only after President Dwight Eisenhower (1890–1969) sent federal troops to the site were the nine students allowed to attend the school. Other states were equally creative. Prince Edward County in Virginia decided to close all of its public schools rather than integrate them. Lawsuits filed on behalf of blacks throughout the South filled the courts. More definitive court rulings ensued, but the road to integration was fraught with many obstacles.

A decade after the Brown decision, southern schools remained 98 percent segregated. Continual agitation on the part of blacks led to the 1964 Civil Rights Act. Thereafter, courts prescribed more immediate and encompassing integration efforts. Starting in 1966 with United States v. Jefferson County Board of Education, the Fifth Circuit Court not only ordered integration but also reme dies to redress historical segregation. In Green v. County School Board of New Kent County (1968), the U.S. Supreme Court ordered schools to provide immediate integration. Similar court rulings, aggressive enforcement by the federal government, and the vigilance of southern blacks eventually led to the racial transformation of schools in the South. By 1970, slightly more than 45 percent of black youths in the South attended integrated schools. Frustrated, however, with the slow pace of integration, in 1971 the Supreme Court ordered a massive urban desegregation plan in Swann v. Charlotte-Mecklenburg Board of Education. In this plan, with the aid of busing, the first district-wide school desegregation order was provided. Busing, as it came to be known, became a very controversial tool to achieve integration.

Busing and forced integration generated considerable fear among many white Americans. This fear resulted in “white flight” (i.e., when whites leave typically urban areas to avoid living in proximity to blacks), and it fueled a conservative backlash against desegregation efforts. During the 1970s, some Republican politicians, such as Richard Nixon (1913–1994), would ride the waves of this backlash all the way to the White House and control of both houses of Congress. These conservative forces also oversaw the first set of reversals. By 1974 in Milliken v. Bradley, the Supreme Court blocked a Detroit area busing plan. In this and subsequent cases, the courts ruled that local decisions regarding school integration should be respected.

As segregation was challenged in the North, the Supreme Court would institute even more radical moves, inaugurating the era of busing, teacher integration, gradual integration, and magnet schools. Although partial success may be claimed, more than fifty years after Brown, little progress has been made toward the racial integration of America’s school system. White flight, private schools, and the more recent voucher movement have all served to preserve racial segregation in schools.

DESEGREGATION IN PUBLIC ACCOMMODATIONS

Access to public space and private dwellings has long been disputed terrain in the United States. Property and the access to property has been the determinant not only of status, but also of political and social rights and privilege. In the United States, the rights to vote, hold political office, and seek legal recourse were all initially reserved for those who owned property. Thus, the first sets of laws aimed at controlling blacks included laws that not only declared them property but also restricted their ownership rights.

The battle to gain access to the totality of American liberties would be incomplete without access to public accommodations. Black Americans pinned their hopes of total freedom on the Thirteenth, Fourteenth, and Fifteenth Amendments to the U.S. Constitution, which together granted them full citizenship. In Plessy v. Ferguson, the Supreme Court declared that black Americans would retain the stigma of race and second-class citizenship, and be denied even basic access to public accommodations. This ruling, more than any other single action, led to the dissolution of good will, the dismantling of postwar Reconstruction, and the wholesale creation of the extensive apparatus of Jim Crow segregation under the misbegotten rubric of “separate but equal.” It would take almost a half-century, several hundred Lynchings, and countless court cases before Plessy would be overturned.

The 1964 Civil Rights Act put an end to segregated lunch counters, hotels, trains, buses, and theaters. This legislation owes its enactment to the courage and determination of many who became heroes of the modern civil rights movement. One such hero was Rosa Parks (1913–2005), who on December 1, 1955, challenged the whites-only Jim Crow laws of Montgomery, Alabama, by refusing to give her seat on a bus to a white patron. Her courageous action launched the modern civil rights movement.

On February 27, 1960, four black college students in Greensboro, North Carolina, defied the laws of segregation by sitting down at a whites-only Woolworth’s lunch counter and requesting service. Although they were not served, their defiance sparked similar acts in over one hundred American cities throughout the 1960s. In 1961 civil rights activists known as “Freedom Riders” began to protest the whites-only policies in public bathrooms and buses. In May 1961 thirteen Freedom Riders, white and black, left Washington, D.C., in two buses heading south.
Riders on the first bus were attacked by pipe-toting men in Anniston and Birmingham, Alabama. The second bus was fire-bombed just outside of Anniston. Undaunted, sit-ins, freedom rides, and other forms of protests compelled a reluctant Congress and president to pass and sign into law the 1964 Civil Rights Act.

DESEGREGATION IN MILITARY INSTITUTIONS
Black Americans have consistently put their lives on the line in defense of their country. However, their service was for many years dismissed, isolated, and segregated. Notwithstanding the valor of such revolutionary-era heroes as Crispus Attucks, a patriot killed by British soldiers in Boston in 1770, General George Washington in 1775 officially barred blacks from serving in the Continental Army. This order, reflecting the legal view of many in the colonies, was followed by the 1792 Congressional Act, which barred blacks from serving in state militias. Congress also prohibited the Marine Corps from its inception in 1798 from recruiting blacks.

Ironically, the First Rhode Island Regiment, formed in 1778, was composed almost entirely of former black slaves. Furthermore, unlike the Continental Army, the Continental Navy recruited heavily among blacks, both free and slave. These sailors, sought for both their skills and to fill major gaps, served with distinction throughout the revolutionary period. Late in the Revolutionary War (1775–1783), in response to British recruitment among slaves, Washington reluctantly eased the ban on the recruitment of slaves. These blacks, however, served in segregated regiments under white officers.

Although blacks have served with distinction and honor throughout American history, their service was typically ignored and downplayed. The U.S. military remained segregated until shortly after World War II (1939–1945), when President Harry S Truman’s (1884–1972) Executive Order 9981 (1948) called for the end of racial segregation in the armed forces. It was not until war broke out in Korea in 1950, however, and the United States faced heavy casualties that the military decided to act upon this order and create the first racially integrated units.

By 2006, with African Americans filling over seven thousand officer posts and composing 20 percent of all service personnel, the military represents the most desegregated institution in the United States. Finally, while blacks do serve in significant numbers at all levels in the military, their service tends to be restricted to noncombat and communications roles. For example, black service members make up less than 3 percent of the pilots, tank commanders, and special forces personnel. Thus, although the U.S. military is formally integrated, nominal segregation by training, specialty, and duty remains the rule.

DESEGREGATION OUTSIDE OF THE UNITED STATES
Segregation has developed wherever there have been racially based societies. What makes these societal situations different has to do with the relative permeability (perceived or real) of segregation. Thus, countries such as France and England exhibit relatively more racial flexibility than such countries as Australia or South Africa. In both France and England, with the decline in their colonial empires, there were deliberate attempts to integrate a greater number of nonwhite citizens into the cultural, political, and social life. In both France and England, noncolonial persons of color experienced a greater degree of social mobility than former colonial subjects. And while much progress has been made, racial unrest in both countries in the first decade of the twenty-first century indicates that more progress needs to be made.

In contrast, extremely rigid castelike structures of racial segregation have only fallen in the last few decades in such countries as Australia and South Africa. In both of these countries, indigenous persons of color experienced decades of exclusion from power, economic advancement, and education, and they were forced to live in enclaves, reservations, or specially designated communities. While these formal walls of racial discrimination have fallen, informal walls remain as “Coloreds” in South Africa and Aboriginals in Australia continue to seek an expansion of their political, economic, educational, and societal power.

DESEGREGATION, SCHOOL

In *Brown v. Board of Education of Topeka* (1954), the U.S. Supreme Court issued a rare unanimous opinion ruling that racially segregated public schools were inherently unequal and therefore in violation of the Fourteenth Amendment to the U.S. Constitution. As Peter Irons wrote of the *Brown* case and the opinion of newly appointed Chief Justice Earl Warren (1891–1974) in particular, “it was a promise to America’s black children of an education ‘available to all on equal terms’ with that given to whites” (2002, p. xi). However, within a year of *Brown*, southern legislatures and school officials had already begun to defy the Court’s firm but vague ruling that schools be desegregated with “all deliberate speed.”

In 1956 this resistance to integration was epitomized by the state of Arkansas when the state legislature passed an amendment to the state constitution commanding the Arkansas General Assembly to oppose “in every Constitutional manner the Un-constitutional desegregation decisions” in *Brown*. In 1957, when the first nine black students attempted to enter Little Rock’s Central High School in accordance with the court ordered desegregation plan, they were turned away by armed Arkansas National Guardsmen dispatched by Governor Orval Faubus (1910–1994). This defiance of federal law by state and local officials ultimately culminated in *Cooper v. Aarons* (1958), a Supreme Court case where the court reaffirmed the nation’s commitment to racial equality articulated in *Brown*. In a rare opinion bearing the signature of all nine justices, the Court wrote, “The principles announced in [the *Brown*] decision and the obedience of the States to them, according to the command of the Constitution, are indispensable for the protection of the freedoms guaranteed by our fundamental charter for all of us. Our constitutional ideal of equal justice under the law is thus made a living truth.”

The ruling in *Cooper* marked the end of the Court’s patience with attempts to delay the integration of public schools. While southern states and school districts continued to challenge court-ordered school integration, the justices handed down decisions ordering schools to continue along the path toward racial equality under the law.

Some scholars argue that the federal government’s shift from a pro-segregation position to one in support of racial equality in the 1950s and 1960s stemmed more from foreign policy interests and a desire to reshape the cold war world in the image of the United States than from any earnest desire to bring an end to racial discrimination (Dudziak 1988–1989). This may explain why, beginning in the late 1970s and more rapidly since the early 1990s, school segregation is increasing rather than decreasing, yet the federal courts, legislature, and executive branch appear reluctant to intercede on behalf of integration efforts. Nonetheless, for nearly thirty-five years following the *Brown* decision, the law of the land was that race needed to be taken into consideration when assessing the quality and fairness of public education in the United States.

In the decades following *Brown*, federal support for desegregation appeared to be working, albeit slowly. For example, the percentage of black students attending majority white schools nationwide rose from slightly over 23 percent in the 1968–1969 school year to slightly more than 37 percent in the 1980–1981 school year. Similarly, over 64 percent of black children attended schools that were 90 percent or more minority in the 1968–1969 school year. However, this percentage decreased to fewer than 39 percent by the start of the 1974 school year, and was 32 percent by 1988 (Brown 2005).

THE POSTDESEGREGATION ERA

After decades of court orders and state and local laws mandating school integration efforts, as well as resistance to these efforts by primarily white citizens and citizen groups, by the middle of the 1980s, progress toward integration had been made. Yet, American schools in many areas remained starkly segregated, and those that had made strides toward greater integration were rapidly become resegregated by the end of the Ronald Reagan (1911–2004) era in 1989 (Frankenberg and Lee 2002). After touring schools across the nation in 1988, Jonathan Kozol observed in his classic *Savage Inequalities*, “What startled me the most . . . was the remarkable degree of racial segregation that persisted. . . . In no school that I saw anywhere in the United States were nonwhite children in large numbers truly intermingled with white children” (1991, pp. 2–3). The reasons observed by Kozol for this continued segregation include: white flight to suburbs, the establishment of private and parochial education for white children, continued housing discrimination against racial and ethnic minorities, some self-segregation by racial and ethnic minorities, and significant shifts in judicial interpretations of desegregation and antidiscrimination law.

WHITE FLIGHT, AND PAROCHIAL AND PRIVATE SCHOOLS

Throughout many parts of the United States, white children are conspicuously underrepresented in public education. According to the 2000 census, slightly over 68 percent of the under-eighteen U.S. population was non-Hispanic white. However, in the 2001–2002 school year, only about 60 percent of public school children were non-Hispanic white (Brown 2005). Los Angeles, California, provides an even more stark example of this dearth of
white children. While approximately 47 percent of the city's population is white, fewer than 9 percent of students enrolled in Los Angeles Unified schools in the 2005–2006 school year were white. Among the reasons for this disparity are the exodus of white people from areas that are becoming increasingly minority and the proliferation of private and parochial schools as an alternative to desegregated public schools.

In the 1960s and 1970s, cities across the country saw radical changes in the demographic makeup and location of their populations. For example, in the 1960s, the white population of Detroit declined by 350,000 people, while the white population of the surrounding suburbs increased by 350,000. At the same time, Detroit's black population grew by approximately 170,000 people (Irons 2002). As Irons writes, “The phenomenon of ‘white flight’ had already begun in Detroit, as white families with school-age children either moved to the suburbs or sent their children to private or parochial schools” (2002, p. 237). In *The Agony of Education* (1996), Joe Feagin, Hernán Vera, and Nikitah Imani note that in U.S. society, whites are more likely to self-segregate even when opportunities exist to interact with minorities, blacks in particular. This separationist behavior is due, in part, to negative stereotypes that whites harbor about blacks.

The private school movement for whites was particularly evident in the South, where the rigid social customs prohibiting intermingling of the races allowed for blacks and whites to live closer to one another than in other parts of the country where de facto and de jure housing segregation kept the races apart. Thus, when desegregation of public schools was ordered, white people in the South found their children in precisely the same school district as black children. As a 2002 study at Duke University found, private schools have grown in the South since 1960 as a response to school desegregation and the region’s rising affluence.

STEERING, REDLINING, AND OTHER FORMS OF HOUSING DISCRIMINATION

School districts are often based on “neighborhood” boundaries. Accordingly, de facto school segregation is often the result of segregation in housing. Prior to *Brown*, whites were protected from living among minorities through laws restricting where minorities could live. In places where these laws did not exist, white homeowners often banded together and agreed to racially restrictive housing covenants—private agreements that prevented minorities from owning property in particular neighborhoods. These covenants were effectively deemed illegal by the Supreme Court in 1948, however their intentions were kept intact by other social and business practices such as discriminatory mortgage lending; intimidation of blacks and other minorities who sought housing in white areas; steering—the funneling of home buyers by realtors to racially specific areas; and redlining—the practice of a lending institution denying loans, manipulating loan terms, or restricting loans for certain areas of a community. In *The Ethnic Experience*, Grace Pena Delgado and Troy Johnson sum up these processes well: “In the United States, Blacks have been forced into segregated suburbs and channeled into segregated cities through institutionalized discrimination in the real estate and banking industries, racially biased public policies, and persistent White prejudice” (2005, p. 258).

While most of these discriminatory practices were outlawed in 1968 when Congress passed the Fair Housing Act, studies show that they are still practiced and their effects clearly linger. For example, as of 2000, on average in U.S. metropolitan areas nearly 65 percent of all African Americans would have to change residence in order for neighborhoods in these areas to achieve residential desegregation (Iceland et al. 2002).

To a lesser, but still significant extent, minority segregation in education can be attributed to self-segregation in housing by minorities. This is particularly true for recent immigrants who often find it easier to adjust to life in the United States when surrounded by people who are culturally similar. There is also some evidence that affluent black families often choose to live in expensive “all-black” suburbs rather than deal with potential prejudice in predominantly white suburbs.

CHANGES IN THE COURT

In *Miliken v. Bradley* (1974), the Supreme Court ruled against city-suburban desegregation and made real desegregation in education impossible in a growing number of cities experiencing an increase in their minority populations. In *UC Regents v. Bakke* (1978), a blow was struck to policies designed to increase minority representation in public higher education. However, it was not until the late 1980s and early 1990s that significant doctrinal shifts altered the way the Court would evaluate school desegregation. Between 1990 and 1995, the Supreme Court decided three cases in which the desegregation orders of lower-court judges were “terminated” and school officials were subsequently free to adopt “race neutral” school assignment policies and maintain segregated schools without fear of future judicial intervention (Irons 2002). The last of these cases involved a primarily black school district in Missouri in which the conditions were so deplorable that one school official “stated that he would not send his own child to that facility” (Irons 2002, p. ix). Over the 1990s as a whole, the Supreme Court increasingly looked unfavorably upon school desegregation decrees—court
requirements that school districts aggressively pursue desegregation. As Kevin Brown writes, “Since school assignment policies are no longer motivated by a desire to maintain racial and ethnic integration, segregation inevitably increases” (Brown 2005, p. 7).

SCHOOL SEGREGATION IN THE TWENTY-FIRST CENTURY

One of the most striking developments in school segregation at the national level has resulted from a transformation in race and ethnicity in U.S. society. At the time of the Brown decision, the racial debate was most often cast in terms of black and white. This was the case, in significant part, because the legacy of slavery in the South and racial intolerance in the North had long been a biracial issue dealing primarily with the interactions between former slaves and white Americans of European ancestry. Also, throughout the twentieth century, black people comprised the largest racial minority in the country.

However, in the closing decades of the twentieth century, educational discrimination against Latinos began to draw more attention as two things happened. First, Latinos began migrating in greater numbers from the western United States, where they had always been a significant presence, to the Midwest, South, and East. Secondly, Latinos in the United States continued to grow in numbers over these decades, ultimately surpassing African Americans as the single largest minority group in the United States. While issues of school segregation had been of significance in western state courts long before Brown ever made its way to the Supreme Court (see Alvarez v. Lemon Grove [1931] and Mendez v. Westminster [1946]), because of the growing number of Latinos in the United States, the school desegregation debate has become black, white, and brown.

In the first decade of the twenty-first century, schools across the United States continue to be separated along racial, ethnic, and economic lines that are drawn primarily to the advantage of white Americans and to the disadvantage of African and Latino Americans. As Nanette Asimov writes, “Even though no board of education still has the power to exclude students based on ethnicity, the schools’ racial barrier lives on in the segregated lives of the rich and the poor” (2004). In states like California, where changes in state policy have eroded the property tax base, one of the traditional mainstays of educational funding for all public schools, affluent communities have used their economic and political resources to ensure that the schools serving their children have adequate learning materials, technological resources, less overcrowding, and qualified teachers. In comparison, poor and minority school districts without these resources have found themselves left behind. Asimov continues, “Today’s Linda Browns [the lead petitioner in Brown v. Board of Education] are students whose parents cannot afford to supplement schools with computers, books, art classes and equipment as parents in wealthier communities do” (2004).

Even in situations where white and minority children attend the same school, studies have shown that they do not necessarily receive the same quality of education. For example, educational tracking—the placement of students into courses based on their performance in standardized achievement tests—has been criticized for effectively segregating white students, who are more commonly placed on high-achievement tracks, from students of color. Further, there is evidence of teachers being more helpful toward white students and of differential grading of students favoring white students over their minority peers (Feagin et al. 1996)

In the early twenty-first century, most African American and Latino children attended predominantly minority schools, and nearly 40 percent of these children attended schools that are at least 90 percent minority (Brown 2005). These resegregated schools exist in the former Jim Crow South as well as the “liberal” North and the progressive West. The end result of resegregated education in America is an “opportunity gap” that has significant consequences for the educational and life chances of poor students and students of color. As Judith Blau notes in Race in the Schools (2003), public schools operate to the detriment of all students because they are racial settings that reproduce white advantage, rather than equalizing forces in U.S. society.

A 2006 report from the the Civil Rights Project at Harvard University indicates the gap between whites and minorities in education only seems to be widening, and doing so with the tacit support of government officials and the courts (Orfield and Lee 2006). Kozol writes, “the dual society, at least in public education, seems in general to be unquestioned” (1991, p. 4). UCLA’s Institute for Democracy, Education, and Access (2004) adds that this widespread resegregation not only fails the promise for equality made in Brown; these schools do not even live up to the pre-Brown doctrine of “separate but equal” set forth by the Court in Plessy v. Ferguson (1896).

DE SOTO, HERNANDO
1941–

The Peruvian economist, Hernando de Soto, best known for his work on the informal economy and its negative effect on poverty amelioration, was born in 1941 in Arequipa. After his father left Peru in 1948 following a military coup, de Soto was educated in Switzerland and did not return to Peru until 1979. He founded the Institute for Liberty and Democracy (ILD) in Lima the next year and serves as its president.

De Soto has written two major books expounding his ideas: *The Other Path: The Economic Answer to Terrorism* (1986) and *The Mystery of Capital: Why Capitalism Triumphs in the West and Fails Everywhere Else* (2000). For both, the subtitles are as significant as the titles. Terrorism is a topic with which de Soto is familiar. He and the ILD have been attacked (physically, not just intellectually) by the Shining Path, a leftist revolutionary Peruvian movement.

De Soto discusses five mysteries of capital in *The Mystery of Capital*. The three most significant are missing capital, the lessons of U.S. history, and legal failure. The basic argument is that the problems of the poor—whether in Peru, Egypt, Haiti, the Philippines, or elsewhere—are not due to lack of possessions or assets but to lack of legally recognized property rights. His researchers have documented the problems that the poor face in major cities, where it takes too long for them to get a license for a legitimate business and their capital is dead capital, preventing them from benefiting from standardization, legal transferability of property, and the use of property as collateral. De Soto claims that over half the grievances of the poor in Peru concern difficulties of getting legal title to real estate: houses, offices, factories, and agricultural land. He claims that the changes in the developing world since the 1960s rival those of the Industrial Revolution since they have involved a massive migration of four billion people leaving their traditional way of life.

De Soto and the ILD have been involved in designing and implementing programs to empower the poor in many areas of the world: Africa, Asia, Hispanic America, the Middle East, and the former USSR. *The Other Path* (a title chosen as a deliberate antithesis to the Shining Path) argues that the real enemy of the poor is not capitalism or "feudalism" but mercantilism: the predominant system in Europe in the early modern pre–Adam Smith (1723–1790) era and a continuing socioeconomic system in post-
De Soto first developed the ideas behind the informal economy: “informal” because it is not formally recognized by the law but functions outside it. It includes informal housing, informal trade, and informal transport.

De Soto points out the hidden costs of informality and the significance of the law as a determinant of development, and he critiques the redistributive tradition, which he associates with the early mercantilist system. He contrasts the relatively peaceful resolution of socioeconomic problems in England (and the United States) with the much more violent revolutions in France, Spain, and Russia. The unlearned lesson of U.S. history was its implementation of widespread property rights in the late nineteenth century.

Numerous criticisms have been made of de Soto’s theories and of attempts to implement them to empower the poor. He has been accused of favoring a “single bullet” approach, and the statistical basis of his data has been questioned. Some critics argue that it is difficult to establish who owns what in an informal economy and that some ILD reforms (such as those in Bogotá) have not improved conditions for the poor. Critics also argue that de Soto ignores the importance of culture and that, while he may be correct in his vision of property rights, the sequencing of reforms is just as important as the need to pay attention to local social context.

In response de Soto (as well as a prominent colleague of his, Madeleine Albright, former U.S. secretary of state) have countered that arguments for the importance of legally recognized property rights do not imply “a silver bullet” but a “missing link.” De Soto argues that heads of state want his help in quantifying the informal sector and that ILD is the only organization doing such detailed research. Perhaps the best summary of de Soto’s views would be that he has the correct diagnosis but an as yet imperfect prognosis; nevertheless, he has started the important process of documenting the (legally) unrecognized assets of the poor.

DESTABILIZATION

The concept of destabilization implies that there is something that is destabilized. What, then, is this “something”? It should reasonably be an “order” of some kind. But what kind of “order”? The Polish sociologist Zygmunt Bauman argues that the current age is one of “floating modernity,” meaning that flexibility and mobility now permeate societal and private life. Employment contracts are becoming increasingly short-term; uncertainty—in both positive and negative meanings—has become epidemic; and the belief of permanent happiness is being replaced by the belief of episodic enjoyment. Changing jobs, once looked down upon, is now seen as something positive and good for personal development. Temporary relationships have gained an increased legitimacy, with divorce becoming a part of everyday life. During early modernity, workers started their careers at one company and often ended them at the same place. In an era of floating modernity, however, where one starts one’s career is no longer a guide to where it will end.

From a societal standpoint, destabilization thus means that power elites become less and less permanent, and that power becomes more difficult to define. This change in power relations means that individuals’ identities vary more and more over time, and that the dominant norms place the temporary, not the permanent, in a primary position.

What are the causes of destabilization? The communications revolution has affected destabilization and individualization in a number of ways—by changing the
Determinants

significance of the territory, by improving the possibilities for network cooperation both within and outside of nation-state borders, and by increasing the significance of innovation and flexibility as a means of productivity and competition. The place of the individual in social, political, and economic networks determines the extent of power that the individual possesses or might exercise. Since the networks are dynamic (or instable), and since individuals can move in and out of these networks, there are no longer any stable power elites. Characteristics belonging to the individual, such as knowledge and education, thus become decisive for corporations and for the economy. Whether a specific individual fits into one of these networks is determined by the individual’s personal characteristics, knowledge profile, originality, creativity, and entrepreneurial skills. Because innovation, creativity, and specialized knowledge form the basis of productivity, every supplier of knowledge becomes a unique carrier of surplus generating competencies. This creates power positions and self-interests, and it helps the information producers become global actors. In addition, short-sighted profits from the stock and currency markets become more important than long-term direct investments. Essentially, cultures are no longer created and shaped by people who share the same time and space, but by individuals who construct their own values on the basis of their own experiences in a world that is constantly being rearranged. In modern parlance, one “is” one’s experiences, and these experiences give rise to the self.

It is fruitful to analyze destabilization in terms of three concepts: power, identity, and norms. Power elites have become changeable and difficult to define, and nation-states are being challenged by different groups of actors who create temporary alliances to further specific issues. Within nation-states, traditional power elites are being challenged by loosely organized networks, which also create temporary alliances.

In addition, the identities of individuals vary more and more over time. This is especially true for those groups of people who actively use the possibilities that the communicational revolution and network society creates. The norms emphasize the short term instead of the long term, impressions instead of experiences, and freedom of action instead of predictability or safety.

As with the concept of individualization, “power,” “identity,” and “norms” are not at the same analytical level. Changes in identity and norms must be considered as part of the destabilization process implying that power relations have become more diffuse and varying. Identity changes in pace with changes in power relations, and the modern emphasis on the short term, happenings, and freedom of action in societal norms is connected with the modern transience of power.

DETERMINANTS

As used in mathematics, the word determinant refers to a number associated with a square matrix, that is, an array of numerical quantities arranged in, say, $n$ rows and $n$ columns. Matrices of this sort typically arise as a means for representing the coefficients in a system of $n$ linear equations in $n$ unknowns.

Suppose the system of equations is

$$
\begin{align*}
& a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n = b_1 \\
& a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n = b_2 \\
& \vdots \\
& a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n = b_n 
\end{align*}
$$

Then the matrix of detached coefficients

$$
A = \begin{bmatrix}
    a_{11} & a_{12} & \cdots & a_{1n} \\
    a_{21} & a_{22} & \cdots & a_{2n} \\
    \vdots & \vdots & \ddots & \vdots \\
    a_{n1} & a_{n2} & \cdots & a_{nn}
\end{bmatrix}
$$

is said to be nonsingular if and only if its determinant is nonzero. The existence and uniqueness of a solution to the system of equations are determined by the nonsingularity of $A$. If $A$ lacks this property, it is said to be singular, and when this is the case, the system might have no solution (nonexistence) or infinitely many solutions (nonuniqueness).
Determinants

The determinant of a square matrix $A$ is the number

$$\det(A) = \sum_{i=1}^{n} (-1)^{i+j} a_{ij} \det(A(i \setminus j))$$

where $A(i \setminus j)$ denotes the submatrix obtained from $A$ by deleting its $i$th row and $j$th column. This definition of the determinant uses what is called expansion by a row, in this case by row $i$. There is an analogous definition of $\det(A)$ in terms of expansion by a column, say $j$, which says

$$\det(A) = \sum_{j=1}^{n} (-1)^{i+j} a_{ij} \det(A(i \setminus j)).$$

These formulas are associated with the name of the French mathematician Pierre-Simon Laplace (1749–1827). From either of them it is evident that the determinant of the identity matrix $I$ is 1, and hence it is nonsingular.

The determinant of a square matrix $A$ and that of its transpose $A^T$ are always equal. Moreover, the determinant of the product of two square matrices is the product of their determinants. In symbols, if $A$ and $B$ are two $n \times n$ matrices, then

$$\det(AB) = \det(A) \det(B).$$

From this and the fact that the determinant of the identity matrix $I$ is 1, it follows that when $A$ is nonsingular,

$$\det(A^{-1}) = \frac{1}{\det(A)}.$$

Thus, the determinant of a nonsingular matrix and that of its inverse are reciprocals of each other.

As can readily be appreciated, the calculation of the determinant of a large matrix by means of a row or column expansion can entail a significant amount of work. Fortunately, there are matrices whose determinants are not difficult to compute. Among these are diagonal matrices (the identity matrix being an example) and, more generally, lower triangular matrices. The determinant of any such matrix is the product of its diagonal elements. (The same is true for all upper triangular matrices.) Finding a determinant is aided by procedures (such as Gaussian elimination) that transform the matrix to another whose structure permits relatively easy calculation of its determinant.

Cramer’s Rule for solving the system $Ax = b$ proceeds from the assumption that $A$ is nonsingular. In that case, the system has a unique solution: $x = A^{-1}b$. Cramer’s rule gives formulae for the values of the components of this vector in terms of the data, specifically as ratios of determinants. The expression of these ratios requires the introduction of a notation for the matrix obtained from $A$ and $b$ by replacing the $j$th column of $A$ by the vector $b$. Let this notation be $A_j(b)$. Then Cramer’s Rule says that for each $j = 1, \ldots, n$

$$x_j = \frac{\det(A_j(b))}{\det(A)}$$

In the system

$$
\begin{bmatrix}
4 & -1 & 3 \\
2 & 0 & 1 \\
-3 & 1 & 5
\end{bmatrix}
\begin{bmatrix}
x_1 \\
x_2 \\
x_3
\end{bmatrix} =
\begin{bmatrix}
2 \\
-1 \\
0
\end{bmatrix}
$$

the determinant of $A$ is 15. The matrices $A_1(b), A_2(b), A_3(b)$ are, respectively,

$$
\begin{bmatrix}
2 & -1 & 3 \\
-1 & 0 & 1 \\
0 & 1 & 5
\end{bmatrix},
\begin{bmatrix}
4 & 2 & 3 \\
2 & -1 & 1 \\
3 & 0 & 5
\end{bmatrix}, \text{ and }
\begin{bmatrix}
4 & -1 & 2 \\
2 & 0 & -1 \\
3 & 1 & 0
\end{bmatrix}
$$

To use Cramer’s Rule in this case, one would compute

$$\det(A_1(b)) = -10, \det(A_2(b)) = -55, \text{ and } \det(A_3(b)) = 5.$$  

Cramer’s Rule then yields

$$x_1 = \frac{-10}{15}, x_2 = \frac{-55}{15}, \text{ and } x_3 = \frac{-5}{15}.$$  

Although Cramer’s Rule is useful in numerically solving small systems of equations (those consisting of two equations in two unknowns, or three equations in three unknowns), it is not recommended for solving larger systems due to the difficulty in computing determinants of order larger than 3. This caution does not apply to situations in which the calculation is entirely symbolic. An example of the latter sort can be found in P. A. Samuelson’s Foundations of Economic Analysis (Harvard University Press, Cambridge, 1963; see equation 7, p. 14).

The task of solving square systems of linear equations arises from least-squares problems which in turn arise in linear regression analysis. The square system is typically of the form $A^T A x = A^T b$. These are called the normal equations. The problem is to find $x$. The first question one faces is whether the matrix $A^T A$ is nonsingular. If it is not—that is, $\det(A^T A) = 0$—then Cramer’s Rule is not applicable. If it is nonsingular, then in principle, the solution is $x = (A^T A)^{-1} A^T b$. When $n$, the number of variables $x_1, \ldots, x_n$, is quite small (and $\det(A^T A) \neq 0$), the use of Cramer’s Rule for solving equations can be considered. But most practical problems of this nature are not small and need to be solved with computers. Since exact arithmetic is then lost, several numerical issues come to the fore. The extensive use of determinants is not advisable simply on computational efficiency grounds. Another consideration, the condition number of $A^T A$, enters the
picture here. As stated by Gilbert Strang, “Forming $A^T A$ can turn a healthy problem into a sick one, and it is much better (except for very small problems) to use either Gram-Schmidt or the singular value decomposition” (Strang 1976, p. 272).

DETERMINISM

Any doctrine positing that one kind or order of phenomena is the necessary and sufficient condition of another kind or order of phenomena is a strongly deterministic doctrine. On the other hand, if a doctrine posits that some order of phenomena is only a necessary or a sufficient condition of another, it is considered to be only weakly deterministic. Since their inception, the social sciences have been home to many such doctrines.

From Arthur de Gobineau (1816–1882) in the nineteenth century to J. Philippe Rushton's work in the 1990s, racist accounts of variations in character or intelligence are among the least credible and most enduring of deterministic doctrines. Psychobiological accounts of the roots of war and violence have had nearly as long a hearing. Somewhat more credibly, contemporary evolutionary psychologists of diverse disciplinary provenance are reviving the pursuit of accounts of humanly universal behavior, as well as of racially marked or ethnically distinctive behavior, as positive adaptations to or resolutions of existential or situational problems (Buss 1999).

The environmental determinism of Johannes Gottfried von Herder (1744–1803), who treated variations of climate and physical environment as the chief source of variations of human character, was popular in the eighteenth and early nineteenth centuries. Herder's latter-day successors are more circumspect, typically treating particular conditions of climate and geography as imposing on the human populations who live with and under them a cap on the upward bounds of politico-economic complexity. A noteworthy case in point is the historian Fernand Braudel's 1949 thesis that the preindustrial societies occupying the borders of the Mediterranean Sea were effectively ecologically precluded from sustaining political organization beyond the level of the city-state.

Technology, however, changes everything, or such at least has been the opinion of a long line of determinists since the heyday of the Industrial Revolution. In the 1930s Braudel's elder colleague Marc Bloch traced the pivotal source of the social organization of French agriculture to the invention of the double-bladed plow. A half-century before, the cultural materialist Henry Louis Morgan had appealed more generally to technological innovation as the essential index of broader civilizational progress. The Victorian biologist and philosopher Herbert Spencer (1820–1903) saw in technological development—first military, then economic—the lynchpin of the advance of utilitarian happiness. Though not quite a utilitarian, Talcott Parsons (1902–1979) was among Spencer's recognizable evolutionist heirs. Less sanguine is the anthropologist Leslie White (1900–1975), who made the post-Hiroshima assessment that the increasing efficiency of the technologies of harvesting energy is the causal underpinning of collective evolution—for better and for worse. White's ambivalence grew darker in such seminal assessments of the harmful environmental consequences of industrial and atomic technologies as Rachel Carson's Silent Spring (1962) and Mark Harwell's Nuclear Winter (1984). In The Condition of Postmodernity (1990), David Harvey argues that the far-flung reach and unprecedented speed of communicative technologies is effecting a global compression of space and time that tends to unmoor human experience from its typically local bearings. Harvey articulates (with a dark ambivalence) a specifically digital determinism.

Cultural determinism of a less material and materialist sort has two prominent installments, both traceable to the early students of Franz Boas. Ruth Benedict (1887–1948) and Margaret Mead (1901–1978) were the early champions of the cultural determination of personality. Encouraging now-discredited distillations of “national character,” their work also gave rise to sustained research into child rearing and other practices that remain the focus of the anthropology and sociology of childhood and education (Whiting and Child 1953; Christie 1999; Jones 1995). Edward Sapir (1884–1939) and Benjamin Whorf (1897–1941) were the eponymous champions of the speculative thesis—erroneously deemed a “hypothesis”—of the linguistic determination of what is presumed to be reality itself. The Sapir-Whorf hypothesis may have had its roots in the thought of such Romantic philosophers as Wilhelm von Humboldt. As an assertion of linguistic relativism or linguistic mediationism, it has many counterparts in semiotics and semiotically grounded theories of knowledge, past and present.
Determinism

Émile Durkheim began *The Elementary Forms of the Religious Life* (1912) with the bold claim that social structure and organization determine the structure and organization of the basic categories of thought. His influence remains most obvious in the work of Mary Douglas. Institutionally more specific, and by far the most influential social determinist, was Karl Marx, especially when writing in collaboration with Friedrich Engels. Marx and Engels’s transference of the presumptive human primacy of a finite set of material needs to that of the institution best disposed to satisfy them—the economy—was the initial step in their theorization of the means and mode of economic production as determinative of the form and content of every other institutional order. Marx’s *Capital* (1867) and his and Engels’s *German Ideology* (1932) were the benchmarks of leftist social and political thought from the turn of the twentieth century until the 1970s. The analysis of the commodity (and its fetishization) in the former treatise stimulated Georg Lukács’s inquiries in the 1920s into the broader capitalist habit of “reification,” the process of construing the related parts of systemic wholes as independent entities in their own right. It would later inspire Max Horkheimer and Theodor Adorno’s critique of the mass-produced debasement of what they called “the culture industry.” The problem of the relation between class interest and truth inherent in *The German Ideology* (1932) gave rise to a Marxist sociology of knowledge from Lenin through Antonio Gramsci and Karl Mannheim to Jürgen Habermas. Especially in its stronger expressions, Marxist determinism brings to an account of human action the same logical assets and liabilities as any other determinism. It is an attractively powerful device of intellectual focus and direction, but it runs two risks: (1) circularity, or taking for granted the very hypotheses that it is obliged to prove; and (2) a drift into the metaphysical, leaving behind any possibility of putting its hypotheses to the test at all.

Determinism, Biological

Determinism, the theory has had cultural and political currency both in the shaping of human racial history and in current debates over the relative importance of our genetic qualities (i.e., nature) versus our socialization process (i.e., nurture) in determining our individual physical and behavioral characteristics.

Although the first traces of biological determinism are suggested in Aristotle’s (384–322 BCE) proclamation in Politics that “there are species in which a distinction is already marked, immediately at birth, between those of its members who are intended for being ruled and those who are intended to rule,” (Baker, 1950, p. 14) it was Enlightenment thinking that ushered in the most robust and politically salient strains of this line of thinking. Using what would consistently prove to be a faulty scientific approach among racial determinists, Carolus Linnaeus (1707–1778) was the first to divide the human race into four categories (red, yellow, white, and black) in 1735. He also began what was to be a trend: racial determinism has never been a project of merely answering questions based in curiosity about human variety; it has always carried a belief in the characteristics associated with these racial categorizations. These beliefs, without fail, served to justify white supremacy in a political context.

Every method of determining a racial hierarchy within the human race has failed to stand up to scientific scrutiny. Nonetheless, such supposed justifications have included measurements of brain size, stature, hair texture, genetic analysis of heredity, and many other measurable attributes. Perhaps the most well-known analysis of this type was Samuel Morton’s (1799–1851) Crania Americana (1839), a selective study of more than eight hundred skulls undertaken to try to prove the innate superiority of Caucasians. A similarly popular work, Essay on the Inequality of Human Races (1853) by Joseph-Arthur de Gobineau (1816–1882), makes an argument in regard to the inherent superiority of the same group, whom he identified as Aryans. “Everything great, noble, and fruitful in the works of man on this earth, in science, art and civilization, derives from a single starting-point, is the development of a single germ and the result of a single thought; it belongs to one family alone, the different branches of which have reigned in all the civilized countries of the universe” (Gobineau [1853] 1970, p. 113). In each examination of racial determinism undertaken by nineteenth-century and early twentieth-century scientists, it has been established that a racist bias at the outset had an impact on the scientist’s findings. Indeed, the history of biological determinism is a prime example of how science is a deeply political practice, despite its claims to universal knowledge.

At the same time, some scientists’ findings have been manipulated by interested parties in order to justify power relations. For example, even though Charles Darwin

(1809–1882) refers to “civilized” and “savage” races as different from one another in On the Origin of Species (1859), he does so as an aside to his major argument that a long process of natural selection has differentiated humans from animals. This claim, however, did not alter the racial determinism of his contemporaries. In fact, his theory became something of a metaphor for those who practiced racial determinism. Darwin’s notion of struggle was generational, and depended on species’ interrelations rather than isolation. However, social Darwinist thinking developed in order to argue that this struggle was actually among races. Herbert Spencer (1820–1903), in particular, jumped on the idea of the “survival of the fittest” to argue not only for white racial superiority, but also for justification of segregationist policies and a lack of social support for nonwhites. For social Darwinists, science had provided a basis on which moral arguments could be made; to create any form of social support (be it charity or state support) for nonwhites would be to contradict the laws of nature. Many social Darwinists felt comfortable with the idea that the inequality of races was a pity, but something that would inevitably lead to the decline and disappearance of nonwhite, and implicitly inferior, races.

Eugenics policies were also based on the ideas of racial determinism. However, unlike the social Darwinists who wanted to allow nature to take its course, eugenicists were more active in their belief in white supremacy. Belief in certain human stock as superior to other human stock (in terms of intelligence, creativity, capacity for self rule, and many other areas) almost always took a racial or ethnic form. While the fascist policy of Nazi Germany is an obvious example of eugenicist thinking, the United States and many other nations have also enacted policies based on eugenics. In the United States, this has meant everything from sterilization of Jewish women upon immigration to the United States, antimiscegenation policies whose selective enforcement prevented white women from bearing children with black and Asian men, and sterilization policies affecting Puerto Rican women after Operation Bootstrap, among many other examples. Many race and gender scholars argue that current policies affecting reproductive rights for poor nonwhite women, while not overtly racist, carry implicit strains of eugenicist thinking.

Biological determinism, while proven to be scientifically invalid in terms of racial categorization and racial meaning, is still present in contemporary debates concerning sexual orientation, genetic research as part of the Human Genome Project, and various overt international policies, such as China’s Maternal and Infant Health Care Law. In fact, an unexpected resurgence of biological determinism has taken place since the mid-1980s, most noticeably with the controversial publication of Richard J. Herrnstein (1930–1994) and Charles Murray’s The Bell Curve (1994). In their book, Herrnstein and Murray argue not only that intelligence is genetically heritable, but also that there are racial and ethnic differences that account for why whites are better off socioeconomically compared to blacks. More recently, Stephen J. Dubner and Steven D. Levitt argue in Freakonomics (2005) that there is a correlation between crime rates and access to abortion. More specifically, the authors argue that greater access to abortion has led to a decrease in the criminally predisposed population. Although a number of scholars, including a few economists, have disputed Dubner and Levitt’s claims, the controversial argument has received national attention and even political notoriety. One example of such political incongruity, based on Dubner and Levitt’s claims, can be witnessed by former Secretary of Education William Bennett’s comment in 2005 on his radio show Morning in America that “if you wanted to reduce crime, you could—if that were your sole purpose, you could abort every black baby in this country, and your crime rate would go down.”

While scientific research about hormones, genes, and other human biological characteristics warrants continuation, social scientists largely accept the idea that social rather than biological or genetic forces drive human choices, human diversity, and the various ways in which difference is both perceived and translates into issues of equality. Of the scholars whose work has stood in opposition to biological determinism, most notable are Ashley Montagu (1905–1999), a distinguished British anthropologist whose early writings in the 1940s and 1950s questioned the validity of race as a biological concept; Stephen Jay Gould (1941–2002), an American evolutionary biologist who refuted many of The Bell Curve’s claims in his 1996 book The Mismeasure of Man; and Joseph L. Graves Jr., an American biologist who argues that “the traditional concept of race as a biological fact is a myth” (Graves 2005, p. xxv).

Determinism, Environmental

Environmental determinism proposes that physical environmental features alone cause human social and cultural behaviors. These features and their changes over time include: climate and temperature; land and soil conditions; rainfall and other water resources; harvestable wildlife and other natural resources; and levels of competition and predation among species.

HISTORICAL OVERVIEW

Dating to the writings of the Greek philosopher and geographer Strabo (c. 64 BCE–23 CE), environmental determinism became prominent during the late 1800s of the Enlightenment period, when many scholars searched for explanations for and methods to study human behavior and societal organization. Its physical nature premise, which was one among many competing for theoretical hegemony, was based on the evolutionary biology of Jean-Baptiste de Lamarck (1790–1869) and Charles Darwin (1809–1882). Lamarck believed that characteristics acquired by habits and other behavioral adaptations to changes in the environment could be genetically transmitted to offspring. (This idea was the precursor of biological or genetic determinism.) Darwin was strongly influenced by Lamarckism, as well as by the population dynamics described in An Essay on the Principle of Population by Thomas Malthus (1766–1834), and by ideas regarding natural selection introduced by Alfred Russell Wallace (1823–1913). Darwin explained in his 1859 book On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life how biological evolution of a species occurred as a result of its population’s environmental adaptation. In this adaptation process, traits that contribute to a species’ competitive struggle for survival are naturally selected and reproducively transmitted to future generations.

These ideas and the development of scientific positivism had a profound impact on Enlightenment thinking. According to Richard Hofstadter, “Darwinism established a new approach to nature and gave fresh impetus to the conception of development; it impelled men to try to exploit its findings and methods through schemes of evolutionary development and organic analogies” (1955, p. 5). Among the social philosophers who saw immediate opportunities to apply Darwinian principles and scientific empiricism, Herbert Spencer (1820–1903) led the way to conceptualize society as an evolving social organism whose change from one stage to the next was the basis of social progress. Within this perspective, known as social Darwinism, Spencer reconciled the dualistic problem of natural and human processes by placing humankind within nature and subjecting it to the same natural laws of competition and survival of the fittest. Meanwhile, other scholars counter-argued for the distinctiveness of social phenomena, which they considered to be sui generis. They believed phenomena such as social behaviors, beliefs, norms, society, and culture are socially constructed products based on human rational choices and collective interaction.

During and after the 1880s, however, European naturalists and social scientists struggled to explain the causes of different levels of societal and cultural variation within and across different geographical spaces. Carl Ritter (1779–1859) incorporated social Darwinism to argue in his nineteen-volume Die Erdkunde im Verhältniss zur Natur und zur Geschichte des Menschen (The Science of the Earth in Relation to Nature and the History of Mankind) written from 1817 to 1859, that these differences were attributable to a nation’s pursuit of Lebensraum (living space) as a biological necessity for its growth. Frederick Ratzel (1844–1904) later expanded the concept’s meaning to propose the idea of the “organic state,” which included human cultural evolution and the diffusion of ideas that occurs as a growing nation acquires more territory and natural resources, greater societal complexity, and higher levels of culture and civilization to meet its needs. The imperialist histories of Great Britain and Germany were often the benchmarks in comparative historical studies. Environmental determinists justified national expansionism by suggesting that primitive societies culturally benefited from contact with more civilized nations. The racist implication of this hierarchical reasoning was that primitive societies, especially those located in the equatorial latitudes, were inferior and culturally lethargic compared to the Nordic races of highly industrialized Northern Europe.
Environmental determinism still had a following, albeit minority, during the early 1900s. Ellen Churchill Semple (1863–1932), a former student of Ratzel and a reluctant social Darwinist, introduced his theory into the mainstream of American geography, though she rejected his idea of the organic state and established her own course. Her most prominent books, *American History and Its Geographic Conditions* (1903) and *Influences of Geographic Environment* (1911), were widely acclaimed (Colby 1933). Throughout her work, which was best known for studies of rural Kentucky, she applied scientific methods to demonstrate that geographic factors worked directly to influence the expression of racial characteristics and indirectly to define a people’s psychological, social, political, and cultural characteristics (Peet 1985, p. 319). This racial theme, or “scientific racism,” was promoted during the next three decades particularly in the climatic determinism of Ellsworth Huntington (1876–1947) and in ethnographic studies conducted by Griffith Taylor (1880–1963) on Australia, Canada, and Antarctica. It even provided the Nazi regime with a convenient but distorted justification for its geopolitical and eugenic policies during the late 1930s and early 1940s. Although racist overtones were discarded in later decades, environmental determinism appears in a few contemporary studies by American geographers and other scholars (e.g., Frenkel 1992; Diamond 1999).

**COUNTERARGUMENTS**

Many geographers and social scientists either eschewed or eventually divorced themselves from both social Darwinism and environmental determinism. Others eased into less apologetic possibilistic and probabilistic perspectives that viewed environmental factors as one among many influences on human choices and on the probable development of particular cultural patterns, dependent on specific social and economic conditions (Lewthwaite 1966). They charged that such a singular deterministic explanation (environmental or otherwise) is insensitive to epistemic differences among cultural, social, and psychological phenomena and the variations in ecological conditions. The anthropologist Franz Boas (1858–1942) argued, for example, that all humans have the same intellectual capacity, all cultures are based on the same basic mental principles, and phenomena have meaning only in terms of their human perception or experience. He distinguished between the physical sciences, which seek to discover natural laws, and the historical sciences, which seek to achieve a comprehensive understanding of phenomena in their own contextual terms. For him and many other scholars, environmental determinism failed to offer a theory of human consciousness and purpose, as well as explanations of differences in and histories of societal organization and processes (Peet 1985, pp. 328–329).

DETERMINISM, GENETIC

Genetic determinism is the notion that an individual's genetic makeup equates to behavioral destiny. This definition is slightly different from one stating that all human beings have the same genetic blueprint. The classic textbook *Gray's Anatomy* illustrates and, indeed, medical scientists rely for treatment upon, a genetically determined, universal description of the human body. All normally developed humans have eyes for seeing, hearts for pumping blood, and so on, as specified by this genetic blueprint.

Behavioral genetic determinism is an extreme form of nativism that emphasizes the innateness of knowledge. Historically, nativism has been contrasted with empiricism, which emphasizes the environment as the source of knowledge, learning, and behavior. A modern doctrine of empiricism is found in British philosophy of the 1700s and 1800s, which argued that humans are born with no innate mental content, equating the mind to a blank slate for experience to write upon. Modern nativism did not emerge until Charles Darwin (1809–1882) proposed in 1859 that, through natural selection, humans are descended from other life forms. In the social sciences, initial support for nativism was provided by William James (1842–1910), who argued that humans have more instincts than animals, thus shattering the dichotomy between instinct and reason. At that time it was believed that animals were instinctive and unintelligent, whereas humans were rational and intelligent. The pendulum swung back to empiricism when behaviorism, a new paradigm in psychology, emerged and endorsed domain-general learning through simple conditioning procedures as the source of all knowledge. Psychology, anthropology, and sociology endorsed this position for much of the twentieth century.

Contrasting genetically determined versus environmentally determined explanations of behavior is analogous to the long-standing debate that incorrectly pits nature (genes, instincts, adaptations, biology) against nurture (environment, experience, general learning mechanisms, culture). Anthropologist Edward Hagen (2005) argues, however, that nature is a product of nurture, and that nurture is a product of nature. To illustrate this statement, one must examine evolution through natural selection. Hagen compares natural selection to a learning algorithm that uses information from the environment to select gene combinations that aid in reproduction. These gene combinations are stored in the genome as this learned information forms the basis of an adaptation. Because adaptations are the product of environmental influences, and are designed by natural selection over evolutionary history, it would be uninformed to discuss genes or adaptations without knowledge of the context in which they evolved. In this way, nature is a product of nurture.

At the same time, nurture is a product of nature. It is unlikely that a truly blank-slate version of the mind would be able to learn anything from the environment. This was the nativist argument advanced by anthropologist John Tooby and psychologist Leda Cosmides (1992) regarding the functional design of the mind. Tooby and Cosmides argued that learning and behavior depend on content-dependent information-processing mechanisms and that once a specialized psychological architecture is in place, adaptive challenges can be met with ease. All humans have a universal, species-typical mind, in the same way that all humans have a universal, species-typical physical anatomy.

One way to illustrate this universal architecture is to examine fear. In an experiment designed by psychologist Susan Mineka and colleagues (1980), infant rhesus monkeys were exposed to one of two videotaped scenarios, one depicting a monkey reacting in terror to a snake, the other depicting a monkey reacting in terror to flowers. Monkeys that viewed the tape showing the reaction to a snake quickly acquired a fear of snakes, but monkeys that viewed the tape showing the same reaction to flowers did not acquire a fear of flowers. It appears that humans also are prepared to learn quickly which features in the environment are threatening and ignore those features that are not. Common phobias in humans include spiders, darkness, and snakes, all of which were adaptive threats in ancestral environments. Learning is not an explanation of behavior, but behavior requiring explanation. The explanation lies in an evolved psychology and the specific problems this psychology has been designed to solve.

Disgust also provides an example of the nature/nurture interaction. Psychologist Paul Ekman (1980) demonstrated that disgust is an emotion that is experienced universally, and the facial expression showing disgust is a reaction that is recognized universally by others. Paul Rozin and April Fallon (1987) hypothesized that disgust is a human adaptation designed to prevent parasites and disease from entering the body. Rotten meat is disgusting to all humans because if consumed it would probably lead to illness. Many species of flies, however, find rotten meat appealing because flies have different evolved mechanisms. Not all cues are as obvious to the human senses as rotten meat, however. With thousands of potentially edible fruits and plants, it would have been beneficial to use the reactions of others when deciding what to eat, rather than relying on a trial-and-error learning system. If a harmful substance is sensed, the body will expel and withdraw from the substance and the disgust face will be made. Other individuals will benefit from this disgust reaction only if they are equipped to pair the disgust face
to the disgusting substance, and learn to avoid it. Again, learning is guided by a universal psychological architecture and explained according to the adaptive challenges it has been designed to solve.

If all humans have the same design of the mind, does that mean human behavior is genetically determined? Adaptations have a genetic basis. However, Hagen argues that because the mind contains many adaptations, all of which respond to cues in the environment, the mind could encompass an enormous number of states with an enormous number of behavioral outcomes. Because humans have an evolved fear of snakes does not mean that everyone is destined to fear all snakes in all situations. Many people have an affinity for snakes, even allowing them into their home as pets. Adaptations do not limit behavior, but instead enable behavior and create behavioral flexibility because a larger set of adaptations can respond with a greater array of behavioral outcomes. Insights from biology, cognitive science, ecology, anthropology, and psychology have been combined to examine genes from an adaptationist perspective in the emerging discipline of evolutionary psychology. Strict genetic determinism is rejected in favor of an account of human behavior that includes both genetic and environmental influences.

DETERMINISM, NONADDITIVE

The principle of nonadditive determinism derives from the literature on integrative, multilevel analyses, which extend across levels of organization (e.g., psychological, physiological, cellular) and analysis (e.g., behavioral, neurophysiological, molecular). The principle of nonadditive determinism specifies that properties of the whole are not always readily predictable from the properties of the parts (see Cacioppo and Berntson 1992). Some properties of crystals (e.g., table salt) cannot be predicted from the characteristics of the individual elements (sodium and chloride) in isolation. Those properties become known only when the elements are found in association or interaction with others. A behavioral example comes from the considerable individual differences that are apparent in the effects of drugs. Some individuals are more affected by, and at greater risk for addiction to, cocaine or other drugs of abuse. Similarly, studies with primates have shown that some monkeys work harder and self-administer more cocaine than others (Morgan et al. 2002). This is not mere random variation, but relates to the animal’s social status—submissive animals show higher levels of cocaine self-administration than dominant animals. This is now understood to be attributable to reciprocal interactions between social dominance, brain dopamine function, and drug reward processes. The important point is that social status, which serves as the informative and organizing construct in this literature, could not be determined in the absence of behavioral measures in a social context.

Even if the properties of, for example, Beethoven’s Ninth Symphony can be fully specified through reference to lower-level physical characteristics (i.e., time-varying frequencies), the composition’s aesthetic features may be more readily apparent or appreciated through higher-level auditory perception. This presence of higher-level aesthetic processes defines a functional quality of the acoustic signals that might otherwise escape recognition. It also serves to focus attention on the important interactions among levels of organization and analysis that may ultimately contribute to the development of a science of aesthetics.

Reciprocal determinism is a related construct. Reciprocal determinism is the mutual back-and-forth interaction among distinct levels of organization (e.g., behavioral and cellular) that requires consideration of both levels for a comprehensive understanding of either. Hormones, for example, can have notable psychological effects, but it is also the case that psychological variables can powerfully impact hormone levels. It is this reciprocal back-and-forth interaction among levels that often under-
lies nonadditive determinism, in which the whole can seem to be more than the sum of its parts.

Nonadditive determinism is not inconsistent with genetic determinism. Drug administration is subject to potent genetic determinants, related to dopamine functions as well as a range of other heritable characteristics, including behavioral variables that contribute to dominance status. Rather, nonadditive determinism is orthogonal to genetic determinism—that is, the two operate independently but simultaneously, emphasizing the multiple levels of organization that interact in the manifestations of genetic (as well as environmental) determinants. Genetic determinism focuses on the gene and gene products, whereas nonadditive determinism emphasizes the structural and functional architectures through which genetic and environmental factors determine outcomes and behaviors.

DETERMINISM, RECIPROCAL

In 1986 the psychologist Albert Bandura put forth a social cognitive theory of human behavior in which human functioning is viewed as the product of a dynamic interplay between personal, behavioral, and environmental influences. This interplay is the foundation of reciprocal determinism, the view that (a) personal factors, such as habits of thinking, emotions, and biological characteristics, (b) human behavior, and (c) environmental forces influence each other reciprocally.

This reciprocal nature of the causes of human functioning makes it possible to direct attention at people’s personal, environmental, or behavioral factors. In school, for example, teachers can foster the competence and confidence of the students in their care by improving their students’ emotional states and by correcting their faulty self-beliefs and habits of thinking (personal factors), enhancing students’ academic skills and self-regulatory practices (behavior), and altering the school and classroom structures that may work to undermine student success (the environment).

Social cognitive theory stands in contrast to views of human functioning that overemphasize the role that environmental factors play in the development of human behavior. Behaviorist theories, for example, show little interest in self-processes because theorists assume that human behavior is caused by external forces. Inner processes, which are viewed as transmitting rather than causing behavior, are dismissed as redundant factors in the cause and effect workings of behavior. For Bandura, people make sense of their psychological processes by looking into their own conscious mind.

Similarly, social cognitive theory differs from views of human functioning that overemphasize the role of biological factors. Although it acknowledges the influence of evolutionary factors in human adaptation, the theory rejects the type of evolutionism that views human behavior as the product of evolved biology. Instead, reciprocal determinism posits a bidirectional influence between evolutionary pressures and human development such that individuals create increasingly complex social and technological innovations that in turn create new selection pressures for adaptiveness. These new selection pressures result in the evolution of specialized biological systems for functional consciousness, thought, language, and symbolic communication. It is this bidirectional influence that is responsible for the remarkable intercultural and intracultural diversity evident on the planet.

Rooted within Bandura’s conception of reciprocal determinism is the understanding that individuals are imbued with the personal factors that define what it is to be human. Primary among these are the capabilities to symbolize, plan alternative strategies (forethought), learn through vicarious experience, self-regulate, and self-reflect. These capabilities provide human beings with the cognitive means by which they are influential in determining their own destiny. The capability that is most distinctly human is that of self-reflection, for it is through self-reflection that people make sense of their experiences, explore their own cognitions and self-beliefs, engage in self-evaluation, and alter their thinking and behavior accordingly. Through self-reflection people also assess their own capabilities. These self-efficacy beliefs provide
the foundation for human motivation, well-being, and personal accomplishment because unless people believe that their actions can produce the outcomes they desire, they have little incentive to act or to persevere in the face of difficulties.

DETERMINISM, TECHNOLOGICAL

From a social-science perspective, technological determinism can be an exasperating concept. Its underlying premise—that technological invention and development are independent causal factors driving change in human history—reduces individuals, society, and culture to mere epiphenomena of a basic, autonomous force. Although the concept suggests that history is overdetermined, at least in its extreme form, the simplicity, tangibility, and rhetorical power of the central argument explains its popular impact. Yet the academic debate also remains lively, as the concept addresses fundamental questions about modern society.

In Does Technology Drive History? (1994), a key text tackling the concept, Merritt Smith and Leo Marx place the various approaches to technological determinism along a spectrum between the extremes of hard and soft determinism. Hard determinists assign agency—the power to effect change autonomously—to technology itself, and to the institutions and structures built to facilitate it. Soft determinists still treat technology as a locus of historical agency—operating within a complex economic, political, and sociocultural matrix—but, crucially, not as an autonomous locus.

Merritt Smith also focuses on three individuals whose work, he argues, is central to the debate: Lewis Mumford, Jacques Ellul, and Langdon Winner. Of the three, Ellul's position is perhaps the “hardest.” His characterization of “technological society” is almost as totalizing as it is pessimistic. It sees individual personal liberty as nearly impossible in the face of a fundamentally organized, rationalized, and autonomous world of machines, technological devices, and interlocking institutions and organizations created around them. Mumford and Winner both map out broadly similar scenarios for the emerging technological order, though both take “softer” approaches, finding arguments for some sort of human or cultural agency (albeit limited) within the dominant structure provided by technology. Add in Robert Heilbroner’s classic essay on technology’s central role in society’s historical development, “Do Machines Make History?” (1994), and Raymond Williams’s more humanistic call for technology to be treated as a symptom, rather than a cause, of social change, Television: Technology and Cultural Form (1989), and the stage for the debate was set. And if participants rarely pushed their arguments to the extremes, they nevertheless have slugged it out over the extent to which technology determines, or is determined by, societal change.

The debate has flourished through works examining the role of technologies as varied as weaponry, agricultural implements, and industrial automation in effecting social change. A particularly fruitful topic of debate has been over the role of new information and communication technologies in society, which is closely related to economic studies of how post-Fordism and postindustrial changes have affected Western economies, particularly since the 1970s. The trend since the 1990s has been toward a harder approach to technological determinism under the guise of information theory. The rise of the Internet and satellite communication as a global force has brought back into vogue, both at the academic level and in the popular imagination, the writings of Marshall McLuhan, perhaps one of the most deterministic of all scholars. More recent academic expositions by Manuel Castells and others on the power of the Internet-driven, global network society have built on the ground laid by McLuhan, Daniel Bell, Alvin Toffler, Howard Rheingold, and even Jean Baudrillard, all of whom have enjoyed a significant popular following, as well as scholarly fame.

DETERRENCE

Deterrence is a military strategy in which one actor attempts to prevent an action by another actor by means of threatening punishment if the action is undertaken. Deterrence is, in essence, a threat to use force in response to a specific behavior. While deterrence is an inherently defensive strategy, it does not involve defense; that is, the deterring party does not actively protect its assets or try to prevent its opponent from taking the action, but rather threatens the use of violence to convince the opponent not to act in the first place.

THEORETICAL UNDERPINNINGS

Deterrence can best be understood with reference to the “3 Cs”: capability, communication, and credibility. Any deterrent threat must meet all three criteria to succeed. Capability refers to whether the actor issuing the deterrent threat is capable of carrying out the threat. Thus, the ability to successfully deter depends to some degree on the power of the deterring actor. Capability is, generally, the most straightforward category, as states typically match deterrent threats to their extant military capabilities. States can, however, dissemble by threatening actions requiring capabilities that they do not have, or by claiming capabilities that they do not possess, though subterfuge and secrecy tend to undermine the efficacy of a deterrent threat.

In order for deterrence to work, a state must communicate its threats. If a state does not know that an action is proscribed, it cannot be deterred from taking that action. Communication is therefore essential if states are to know what actions they are not supposed to take, as well as what will happen if the action is taken. Thus, good lines of communication are crucial. The “hot line” between the Soviet Union and the United States during the cold war served this function well. With deterrence, the goal is to avoid armed conflict and communication is vital to create boundaries and reveal expectations.

The final C, credibility, is perhaps the most difficult criterion to meet. Deterrence is, in a sense, a fundamentally irrational action, because the threat is carried out after the violation occurs. Once the forbidden action is taken, it does not necessarily make sense to carry out the threat that was intended to deter that action in the first place. This is similar to the economic theory of “sunk costs,” in which costs that have already been incurred should not be included in decisions about future behaviors. States have to work very hard at establishing their credibility, especially in situations of extended deterrence (explained below), and they often try to “tie their hands” meaning the decision to carry out the deterrent threat is made automatically. During the cold war, the U.S. soldiers stationed in West Germany had no chance of repelling a Soviet invasion of Western Europe. Instead, the troops served as a “tripwire,” ensuring Americans would be killed in any Soviet invasion and increasing the odds that the U.S. would come to the defense of Western Europe, making more credible the American deterrent threat.

TYPES OF DETERRENCE

There are two fundamental types of deterrence: central and extended. Central deterrence occurs when a state attempts to deter attacks against itself, its nationals, or other intrinsic assets. In extended deterrence, a state attempts to prevent attacks against an ally or another third party. Credibility is usually easier to establish with central deterrence, because the need to develop a reputation for protecting one’s own assets is vital to the strength of a state. Credibility is much more difficult to build in extended deterrence, because it is harder for the deterring state to risk war to protect an ally.

Deterrence can also be broken down into two strategic categories: denial and punishment. In a denial strategy, also known as counterforce deterrence, the military deterrence is targeted at the enemy’s military and political assets, such as military bases, command and control assets, and governmental facilities. The purpose of the deterrent is, therefore, to prevent the enemy from achieving whatever goal it seeks with the use of force. If the opponent correctly reads the deterrent threat as sufficiently reducing the likelihood of obtaining the desired outcome, then the action will not be taken and deterrence will succeed. Flexible response, discussed below, is an example of denial strategy.

In punishment, or countervalue, deterrence, the deterrent threat is targeted at the enemy’s “soft” targets, such as population centers or industrial capabilities. The aim of punishment deterrence is to threaten such a high cost to the fabric of the opponent’s society that the action in question will no longer be worth the cost. Both massive retaliation and mutual assured destruction are illustrations of punishment strategies.

DETERRENCE STRATEGIES

While deterrence can be based on both nuclear and conventional forces, deterrence strategy can best be demonstrated by examining the evolution of U.S. nuclear strategy over
time. The first formulation of nuclear deterrence was “massive retaliation,” a punishment strategy created by John Foster Dulles, the U.S. secretary of state under President Dwight Eisenhower. Here, the United States reserved the right to respond to any military provocation with nuclear weapons, and particularly with much greater force than the original attack. The United States was thus relying on its superior nuclear forces to deter the numerically superior Soviet Union from invading Western Europe. The main problem was the inability to deal with minor threats. As the Soviet nuclear arsenal became more capable of matching that of the United States, massive retaliation was replaced, under the Kennedy Administration, with “flexible response,” a denial strategy that created a menu of responses that could be tailored to a specific action. The intent was to make the threatened use of nuclear weapons more credible. However, it was determined that any use of nuclear weapons could escalate into large-scale nuclear exchanges, and flexible response was discarded and replaced with “mutual assured destruction” or MAD. This was a punishment strategy that relied on the ability of both nations to completely destroy each other.

Deterrence is a critical part of the strategic arsenal of countries because all nations usually seek to avoid armed conflict and war. The need to maintain a strong deterrent posture can also inhibit states from achieving other political goals. For example, there was great resistance to the Israeli withdrawals from Lebanon in 2000 and from Gaza in 2005 because of fears that these actions would undermine Israeli deterrence capabilities. However, the years since 1950 have been something of a triumph for deterrence theory, and for nuclear deterrence in particular, as a conflict between the major powers has been avoided.

DETERRENCE, MUTUAL

The concept of deterrence implies that, through threats of raising potential costs through means such as attack or retaliation, a party to a dispute can dissuade an opponent from undertaking an undesired action, such as starting a war. It is difficult to know when an opponent is “deterred,” since one must determine whether the party in question ever actually intended to act and also whether the adversary’s threat dissuaded them. Under mutual deterrence, two or more parties simultaneously deter each other, a process even more complicated to verify.

Mutuality implies that both parties’ threats raise such negative consequences that neither party takes action. Each party must possess both sufficient resolve and capabilities to make threats credible; costs must outweigh any advantages gained by aggressive action.

Deterrence theory stems from the longstanding international relations theory of the balance of power, a much-debated notion that nations try to negate each other’s power advantages by strengthening their own forces and joining offsetting alliances. War supposedly can be averted through a balance of forces, though World War I (1914–1918) and other wars have broken out between powers supposedly engaged in such balances.

The post-1945 advent of mass destructive weapons and the cold war raised the possibility of a “balance of terror” between nuclear-armed alliances. Implicit was the threat that if one side struck with nuclear weapons, the other side would retaliate. Thus both sides would refrain from attack out of mutual fear of destruction. It is debatable whether nuclear standoff or more conventional power and interest calculations preserved the tense thirty-five-year peace between the United States and the Soviet Union.

Mutual deterrence thus took the form of a cold war doctrine of mutually assured destruction. In this remarkable and costly initiative, both Washington, D.C., and Moscow agreed to “harden” their retaliatory nuclear missile forces in impregnable underground silos and submarines at sea to assure that if one side launched a nuclear “first strike,” the other side would surely be able and willing to respond, inflicting unacceptable damage on the initiator. Stable deterrence implied that neither side should do anything—for example, defend its cities—to upset the psychological assurance of effective retaliation.

Game theory became an integral part of the strategic thought accompanying these policies. Scenarios such as the prisoner’s dilemma and chicken games denoted costs and benefits of either collaborating or “defecting” from peaceful strategies. Temptations to build up arms and attack would inspire similar behavior in the opponent; in seeking security through armament, both sides might become less rather than more secure (the so-called security dilemma).

Deterrence in today’s post-cold war world is still premised on assumptions that nuclear-armed adversaries, such as India and Pakistan, are restrained from attack by the possibility of unacceptable damage in return. No such
restraint supposedly applies where only one side is heavily armed. The logic or illogic of unilateral or mutual deterrence remains puzzling, for example, as big powers attempt to dissuade smaller powers and nonstate or "terrorist" organizations from initiating violence. As actors adopt unorthodox forms of violence (e.g., personnel bombings and sabotage), it is not clear when political and social costs inflicted by military reprisals or other means are sufficient to deter further violence.

DEVELOPING COUNTRIES
Developing countries—generally referring to the countries of Africa, Asia, and Latin America—is a term that was inspired by Walt Whitman Rostow’s classic work, The Stages of Economic Growth: A Non-Communist Manifesto (1960). Rostow argued that all countries go through a series of stages of economic development from “underdeveloped” to “developed”; that the United States, Western Europe, and Japan had reached the “highest stage” or “developed-country” status; and that those countries that were not mature, developed capitalist countries were in the process of “developing” and moving through the required stages.

A variety of terms have been used to refer to these “developing” countries. These include less-developed countries, underdeveloped countries, undeveloped countries, backward countries, Third World countries, and newly industrializing countries. Except for Third World, which was advanced in the late 1960s and early 1970s to refer affirmatively to countries that were politically independent of the United States and the Soviet Union, these terms are more-or-less pejorative. Newly industrializing is more specific than the other terms, in that it refers to a limited number of countries that have begun industrializing since the 1970s.

Implicit in the term developing countries is the suggestion that things will improve over (some unforeseeable period of) time. However, this terminology has been used to hide the exploitation and oppression of people in the so-called developing countries—exploitation by corporations headquartered in the developed countries, by dictators installed or supported by the U.S. government or its allies, or by the governments and militaries of the developing countries themselves.

As hinted at by its subtitle, Rostow’s work was designed to support the U.S. imperial project and aimed not only to bypass but to supersedes the Communist concept of imperialism. To Rostow—and to the U.S. government, for which he later worked—the Communist challenge in Southeast Asia was a serious one, especially because the region was deemed of strategic importance. Rostow argued that the lot of poor, exploited, and mistreated peasants in the developing countries would get better over time, whereas the Communists maintained that things could not improve under capitalism—that is, that revolution, not acquiescence based on “hope,” was the only path to a better life.

The upper echelon of the U.S. government saw its post–World War II (1939–1945) project to achieve political, economic, military, and cultural hegemony over the countries of the world—at least those outside of the Soviet Empire—as being threatened by various revolutionary struggles in the developing countries. In response, the United States designed a global strategy of counterinsurgency to undercut indigenous struggles to gain independence (Post 1990, pp. 1–41). Along with this went various forms of ideology and propaganda, a key component of which was the theory of modernization, of which Rostow was the primary proponent.

CRITICAL APPROACHES
One of the first critical thinkers to analyze the true situation of the developing countries was Raúl Prebisch of the Economic Commission for Latin America, who argued that the relationship between developed and developing countries was exploitive. This perspective was further developed by Andre Gunder Frank, who introduced the concept of dependent development. According to Frank, development strategies promoted by the wealthy countries
were designed to ensure that the “developing” countries remained in a subordinate position.

A more systemic and historical perspective was proposed by Immanuel Wallerstein (1974, 1980, 1989). Wallerstein's world-system theory holds that beginning in the sixteenth century, capitalists backed by “strong states” spread outward from Western Europe to control the world, obtaining cheap labor and raw materials through trade relationships that benefited those in the European—and later U.S.—“core” countries. Wallerstein posits three levels of economic development represented by concentric “rings,” moving from the advanced “core” countries to peripheral countries, with the “semi-periphery” located in between.

Despite having generated extensive research, Wallerstein's conceptualization has a critical weakness: While it is quite perceptive, it is a static model. Once a country gets “located” in one of the three “rings,” world-system theory cannot explain how it can move from one ring to another. The case of South Korea is perhaps the most obvious example of a transition world-system theory cannot explain. Wallerstein's model has other problems as well. Historical evidence does not support the existence of a singular world-system—at least before 1989. In addition, Wallerstein's conception is overly simplistic.

A much more interesting approach is that of Jan Nederveen Pieterse (1989). Nederveen Pieterse, who unfortunately did not have the “marketing” acumen of Wallerstein, never named his conceptualization. Yet his book Empire and Emancipation: Power and Liberation on a World Scale (1989) is the best explanation to date of relations between the European and, later, American nation-states and those referred to as developing countries. Nederveen Pieterse argues that to understand European global domination, one must begin by returning to the Crusades, out of which, he maintains, modern “Europe” developed. He carefully considers the processes of European development, taking a poststructural, processual approach instead of a static one. Nederveen Pieterse sees the domination of Europe and the United States as being imperialistic, but unlike Marxists, he does not give primacy to economics: He recognizes imperialism as (1) being a process of domination; (2) being characterized by interaction between economics and politics; and (3) always harming the people in the dominated countries. Interestingly, Nederveen Pieterse does not confine his understanding of imperialism to the nation-state level. Instead, he argues that imperialism is the domination of one political community over another, encompassing not only states, but also supra-states (e.g., the United Nations), subnational communities, and even organizations, such as the AFL-CIO.

Nederveen Pieterse is not satisfied, however, with focusing his analysis on domination alone; he argues that one must also analyze and theorize historical resistance to domination. Thus, he recognizes the Haitian Revolution and its key role in world history, the struggles of Native Americans against Euro-American settlers, and other efforts to resist domination.

**NEOCOLONIALISM AND POSTCOLONIALISM**

With only a few exceptions, such as Ethiopia, Iran, and Thailand (formerly Siam), most of the world's developing countries were formerly colonies. While formal colonization has largely ended, either through the granting of independence or through wars of liberation, many formerly colonized countries have continued their earlier political-economic relationships with their former colonial master. The reason for this is easy to understand: Colonization involved structuring the economy of the colonized country to serve the needs of the colonizing country and its corporations. Local administrators trained during the colonial period know little else, and therefore the old relationships have continued, only under new leadership (the color of the faces is usually all that has been apparently changed, but usually violence against formerly colonized peoples has been drastically reduced, if not ended). This continuation of earlier colonial political-economic relations is generally referred to as neocolonialism. Neocolonial relationships have been encouraged by both the International Monetary Fund (IMF) and the World Bank. Both have promoted neoliberal development programs. This neoliberal economic model has resulted in what Kim Scipes's study of the Philippines from 1962 to 1999 calls “detrimental development” (Scipes 1999).

Perhaps the most interesting phenomena of the late 1990s and early 2000s is the development of postcolonial states. These are states that have decided to develop their respective economies in ways that challenge the hegemony of the U.S.-controlled IMF and World Bank. Great progress has been made by several postcolonial countries, including South Korea, which went from the periphery to the core (using Wallerstein's terminology) in less than thirty years. Venezuela, a major oil-producer, is also currently showing success at developing its economy independently.

Postcolonial development models differ widely. South Korea's rapid industrialization, as impressive as it was, was in large part achieved through extreme exploitation of young women. Venezuela, on the other hand, has set a slower pace of development, and the government of President Hugo Chavez is trying to find ways to improve the lives of Venezuela's people through diverting some of the country's oil profits into social programs. How far
Venezuela can go in meeting the needs of the people, especially in light of U.S. intervention in its domestic affairs, remains to be seen. However, Venezuela’s mobilization of large masses of the population to address their own problems—that is, development from “below,” as opposed to the imposition of state “plans” from above—is an exciting process that holds out the promise of development without oppression.

DEVELOPMENT

Development theory is largely a product of post–World War II (1939–1945) thinking in the social sciences and international policy studies. The key intellectual challenges for development theory are these: What are the causes of economic transformation in human societies? What are some of the policies through which governments can stimulate the processes of economic growth? These questions have been the subject of inquiry within classical political economy for several centuries, and interest in the determinants of growth and modernization has been part of economic theory since its beginnings. But modern development theory took its impulse from global developments following World War II—the needs of reconstruction of Europe and Japan following World War II; the creation of international monetary and trading regimes to facilitate international economic interaction; the circumstances that followed from the dissolution of European colonies in Asia, Africa, and Latin America; growing attention to the persistence of poverty in the developing world; and focus in the 1990s on the phenomena of globalization.

The concept of development has encompassed several separate ideas in the past sixty years: the idea of modernization of economic and social institutions, the idea of sustained economic growth within a national economy, the idea of the continuing improvement of the material well-being of the earth’s human population, the idea of more extensive utilization of the world’s resources, and the idea of the replacement of “traditional” institutions and values with “modern” successors. Some of the large questions that have guided development theory include these: What are the features of society that can be characterized as “modern”? What causes a society to undergo sustained “modernization” and sustained economic growth? What institutional features are important causes in economic development? What steps can governments or other major institutions take to stimulate development? What is the significance of the specific features of western European economic development since 1600? Are there alternative pathways through which “modernization,” growth, and improvement of human well-being can occur? Are there cultural assumptions that are made in valorizing development, growth, and modernization over tradition, moderate consumption, and stable cultural practices? How can one best define the goals of development in terms of human well-being? How should considerations having to do with equality, equity, and justice be incorporated into analysis and policy of development?

Development theory has taken shape through efforts in several areas of the social sciences: economics (theories of efficient markets, trade, and income distribution); sociology (research on concrete processes of social change in different parts of the world); anthropology (research on the values and practices of a range of non-Western cultures); political science (research on the institutions and interests that drive international economic policy); history (research on the dynamic circumstances that created modern national and international economic institutions); and critical social science (focus on features of inequality, power, and exploitation that have often characterized international economic institutions). Each of these strands captures something important about the historical experience of parts of the modern world, and yet they fall short of a full and general approach to the topic of devel-
Development. Development theory is an expansive, eclectic, and interdisciplinary field defined by a diverse set of questions and methods—not an exact subdiscipline within economics.

Decolonization and the aftermath of World War II stimulated a wave of academic and policy interest in the dynamics of economic growth and development. President Harry Truman highlighted the crucial importance of addressing global issues of poverty and hunger in his 1949 State of the Union address, an emphasis that stimulated new United States and international commitments in support of economic development in the decolonized world. The 1950s witnessed a surge of early development theory, in the hands of such authors as Simon Kuznets, W. Arthur Lewis, and Ben Hoflitz. A central thrust of these efforts was the formulation of economic theories of growth that, it was hoped, could help to guide policy in the economic transformations associated with decolonization. Postwar development theory also provided some of the intellectual foundations for the establishment of postwar international economic institutions such as the World Bank and the International Monetary Fund. Much of this work presupposed the idea that there were distinct stages of economic development, and it focused on the relationship between economic growth and savings as the basis for capital formation. The role of trade in economic development also played a central role in these theories. W. Arthur Lewis's theory of the "dual economy" was particularly prominent as a basis for attempting to understand the economies of the previously colonial world. This model postulates an economy consisting of a "traditional" sector (labor) and a "modern" sector (capital). Lewis postulated that firm owners in the modern sector were profit-maximizing, whereas those in the traditional sector were not, and that there was surplus labor in the traditional sector. So a strategy for growth is to induce a shift of economic activity from the traditional to the modern sector. This approach would increase savings and capital formation, leading to growth and rising incomes. Other economists such as Irma Adelman and Hollis Chenery cast doubt on the stage theory and further broadened the perspective by bringing distribution and welfare into the discussions.

There has been emphasis since the 1960s—sometimes waxing, sometimes waning—on the crucial importance of alleviating poverty in the developing world. Throughout much of its history the World Bank has expressed its adherence to the priority of poverty alleviation. The United Nations Millennium Goals for 2005 place poverty alleviation at the center of the development agenda for the coming fifty years. But even placing a sincere priority on poverty alleviation, there is a wide range of disagreement over the steps that should be taken to achieve this goal.

Several important frameworks of thought have been important in development theory thinking. Neoliberal development theory reflects the folk wisdom of neoclassical economic and political theory. Described as the “Washington Consensus,” this approach to development postulates that modern economic development requires free markets, effective systems of law, and highly limited powers of government. The slogan of “Getting the Prices Right” was a rule of thumb for economic institutional reform in countries receiving advice and assistance from international institutions. This school of thought places great importance on free trade within the international economic system. Neoliberal structural adjustment reforms in the 1980s, enforced through International Monetary Fund and World Bank policies, pushed third-world governments toward harsh domestic reforms (currency devaluation, reduction of programs aimed at the poor, elimination of subsidies for rural development, liberalization of trade practices). Critics have argued that these structural adjustment policies have had the effect of further impoverishing the poorest of many developing societies.

Critical of the neoliberal consensus is an influential group of development theorists who emphasize the centrality of human well-being in development theorizing and the crucial role that public policies and expenditures play in successful efforts to improve the well-being of the poor in developing societies. Amartya Sen, Martha Nussbaum, and others argue for placing a nuanced theory of human development grounded in capabilities and functioning at the center of development policy. And they argue for the crucial role that public policy has in creating the human welfare infrastructure that is essential for the successful alleviation of destitution: public health, nutrition, free education, and democratic freedoms. On this view, the narrow conception of the role of the state associated with the neoliberal approach almost inevitably implies further degradation of the conditions of life of the least-well-off in the developing world. A concrete achievement of this approach is the creation and maintenance of the Human Development Index by the United Nations Development Program. This index is designed to provide a measure of economic development that goes beyond measuring growth of per-capita income, and instead focuses on measures that are correlated with quality of life: health, longevity, and educational attainment, for example. Another such measure is the Physical Quality of Life Index.

There have been critical voices within development theory throughout its history. Postwar theories of colonialism emphasize the extractive role that the system of colonial control represented, with a flow of natural resources from periphery to metropole. Dependency theory is the view that the world economy since 1945 has been con-
constructed around a set of institutions that systematically disadvantage the South for the benefit of the North, by structuring production and trade in such a way as to limit economic growth in the third world. The South is integrated into the “modern world system,” but on terms that systemically work to the disadvantage of the countries and peoples of the periphery. The Brandt Report (Independent Commission on International Development Issues, 1980) focused attention on the relations between the wealthy North and the impoverished South. This approach emphasizes structural inequalities, systemic institutional disadvantages, patterns of unequal exchange, and resulting uneven development. A different line of critical thought emerges from cultural critics of modernization. Arturo Escobar is a central voice in this body of criticism. This perspective offers a critique of the discourse and presuppositions of development thinking in the West: the presumed primacy of Western values, the unquestioned importance of consumerism, the teleology associated with the concept of “modernization,” and other ways in which the values and assumptions of development theory reflect unquestioned ethnocentrism and universalism.

The concept of development incorporates several debatable assumptions. First, it has a tendency towards Eurocentrism. The paradigm of development incorporated in much development theorizing is the experience of western Europe during the Industrial Revolution. Non-European societies that undergo “development” (Japan, Taiwan, and Argentina) are frequently categorized in terms of a baseline comparison to the western European experience. Historical research conducted since the mid-1980s casts doubt on this single-track theory. Asian economic development in the seventeenth century and the twentieth century gives substantial evidence of the availability of alternative pathways of development, and there is considerable institutional variation within regions of western Europe itself.

Second, the concept of development is burdened with an implicit teleology. The word implies a progressive transformation from “less developed” to “more developed”; it implies the creation of more complex, sophisticated, and humanly adequate systems out of simpler and less adequate systems. (Rostow’s concept of “stages of growth” captures this assumption precisely.) Historians have long since abandoned the idea that history has directionality, and have demonstrated the many false starts, wrong turns, reversals, and stalls that all societies have experienced.

Third, the concept of development brings with it an idealized set of assumptions in the background about what a “developed” society ought to include: consumerism, democracy, markets for everything, individualism, impersonal legal systems, large complex societies, and a high material standard of living. This is a social ideal that is deeply embedded in development theory and that can be legitimately questioned. The values that are associated with western consumer culture represent one possible framework of human values—but only one such framework. In fact, it may be that the constraints of long-term environmental sustainability make this complex of values doubly questionable.

Finally, development theory has been forced to confront the contradictions between economic growth and environmental sustainability. Resource depletion, destruction of forests and wetlands, urban sprawl, air and water pollution, and global climate change resulting from carbon dioxide emissions all call into doubt the feasibility of permanent economic growth. Prudent multigenerational planning for the future of the planet will require more consistency between the needs of consumption and the needs of environmental sustainability.

DEVELOPMENT, INSTITUTIONAL

In the social sciences, organizational theory, and politics, the term institutional development is often used as a synonym for institutional and organizational change, implying that social transformation occurs in an organizational framework. Institutional development aims at establishing and improving an institutional structural unit and its capabilities, as well as the impact and effectiveness of organizations. This effort is understood as a long-term multiple-stakeholder process in which numerous factors and power relations influence the final outcomes and their everyday relevance. Institutional changes may also be influenced by previous policy practices, and development is shaped by a wide range of stakeholders, including staff capacity and capability, as well as equipment and infrastructure. It is thus increasingly recognized that institutional development must be seen in terms of a longer trajectory. By and large, the long-term process of institutional development must be established in the form of carefully designed projects. Institutional development projects hence address issues as organizational and technological management.

Development issues in the field of education include the setting up, upgrading, and enhancement of course design and curricula and of equipment infrastructure, the establishment of new policies, and the improvement of existing regulations within professional organizations. This process is often supported or even devised by consulting partners. In the field of development aid or, in more general terms, philanthropy, the process of institutional development as practiced, for example, by nongovernmental organizations can be seen as the improvement of an organization’s responsiveness to the needs of its intended beneficiaries, the finer discrimination between different needs, and a quicker response to these needs.

The danger in both fields is that institutions meant to be intermediaries, and thereby a means to an end, are treated as ends in themselves. In the domain of education, this can easily lead to an over-decentralization of education due to different stakeholder interests, and consequently to a loss of societal control over contents or standards. In the case of institutional development in philanthropy, those whose welfare is of ultimate concern may recede into the background.

In evaluating institutions and their impact on outcomes in the field of development aid, high-quality standards have been identified as an important aspect. But institutions do not stand alone. They are embedded in local settings and are influenced by history and culture. So the impact of institutions on developmental progress is framed by particularities of local settings, stakeholder perspectives, time horizons, informal rules, social norms, customs, policies, and so forth, apart from the intention and will to reach a certain development goal. To incorporate these different factors into a specific institutional development project poses a considerable challenge that demands drawing on knowledge gained in the field of cross-cultural psychology and related disciplines.

The designs of institutional development projects vary considerably. Tools and approaches for institutional development include the process approach, total quality management, knowledge management, change manage-
ment, monitoring and evaluation, and formative or summative approaches. Institutional development projects often lead to the conclusion that there are no “recipes” for changing institutions. In some cases, projects may develop guidelines describing tools to be used in practice. A large number of such guides can be found, written, and used by those who are involved in institutional development. All of these have strengths and weaknesses, and need to be adapted in the specific context of application. They reflect different theoretical backgrounds and are usually based on the practical experiences of those who used them while they were adopted. As exemplified in numerous project descriptions and evaluations, the first step to institutional development is always a serious analysis and diagnosis of the organization in its institutional context. Different stakeholder interests must be identified, goals of change or development have to be determined, and the process of change needs to be planned, implemented, and evaluated.

Nevertheless, measuring the success or effectiveness of institutional development remains difficult. Certain pitfalls that tend to occur in the process can be explained by the low standards of institutions initiating the change processes or by the conflicting interests of stakeholders. There are also cases of institutional “stickiness,” where actors fail to respond to changes in the environment. Identifying factors driving institutional development is still a challenging research question. There is a need for a generalization of specific success factors in institutional development based on case studies and best-practice examples. Scientific literature on institutional development is quite dispersed, and no overall state-of-the-art volume is available.

**DEVELOPMENT, RURAL**

Rural development is the process by which sparsely populated areas improve their standing on socioeconomic measures. Political leaders try to hasten the pace of rural development through a wide array of policies. Concern about rural development arises because most rural areas lag behind metropolitan areas on basic indicators such as income, employment rates, and health outcomes. Rural development includes infrastructure, economic capacities, and the ability of local institutions to adapt to change in positive ways.

In the United States prior to the 1860s, action to foster rural development was focused on facilitating the westward movement of people. The emphasis shifted in 1862, when the Morrill Act granted land to states to create colleges with a mission to promote the liberal and practical education of the industrial classes. In 1887 the Hatch Act bolstered the capacities of these colleges, known as “land grants,” to conduct research on improving agricultural practices. In 1914 the Smith-Lever Act established cooperative extension. The cooperative extension system is managed jointly by the land grants and the U.S. Department of Agriculture (USDA), and its mission is to teach the public how to apply land-grant research to improve their lives. Cooperative extension initially focused on agriculture and home economics, but evolved with the changing times and broadened its scope to include rural development functions such as leadership development, small-town development, management of human and natural resources, education of youth, and improving the competitiveness of rural manufacturing. The land grants and the USDA partner in supporting four regional rural development centers, based at land-grant institutions, each focusing on rural development issues in multistate regions.

President Franklin D. Roosevelt’s New Deal policies established the Rural Electrification Administration (REA) in 1935, which brought electricity to most farms within fifteen years of its inception. Electrification greatly improved the quality of rural life and accelerated the industrialization of agriculture. As farming became more industrialized, rural labor was released, creating demands to create other kinds of rural enterprises to occupy the workforce. The New Deal also created the Farmer’s Home Administration (FmHA) to provide loans for farms and rural infrastructure projects. In the mid-1990s the FmHA changed its name to USDA Rural Development to better reflect the full portfolio of its activities.

Although various rural development programs enjoyed some success in developing nonfarm jobs, they could not produce enough jobs to employ all the people leaving agriculture, and rural people began to move to cities. From the 1950s onward, major rural issues have been how to adjust to population decline in rural areas located far from metropolitan areas, and how to mitigate sprawl and the accompanying loss of the land base in metro-adjacent areas. These issues sparked activism and
generated grants from organizations such as the W. K. Kellogg Foundation, the Farm Foundation, the Rural School and Community Trust, the American Farmland Trust, and the National Association of Towns and Townships. State and local governments also responded by supporting creation of local economic-development authorities and land-use planning authorities.

Although some concerns about the rural areas of the United States remain, the rural quality of life is far better in the United States than in many other areas of the world. Since the late 1940s there have been attempts to apply the lessons learned in the United States to less-developed countries. The movement began after World War II (1939–1945), when the successful reconstruction of war zones through the Marshall Plan convinced U.S. policy makers and others that foreign development assistance could be effective. At the same time, policy makers began to notice the impact that Norman Borlaug (with support from the Rockefeller Foundation) was having in reducing famine in Latin America and Asia through improved varieties of cereals, in what came to be known as the “Green Revolution.” (Borlaug was awarded the Nobel Peace Prize in 1970 for his work.) The internationally funded World Bank, the United States Agency for International Development, and similar agencies from other wealthy countries began to fund agricultural and rural development projects in many low-income countries. The projects included long-term support for internationally distributed basic agricultural research through the fifteen centers of the Consultative Group on International Agricultural Research, and associated projects to mitigate the negative impacts of increased technology in agriculture, such as increased dependence on purchased inputs, a higher rate of social inequality due to faster adoption rates among wealthier households, and the environmental consequences of increased cropping areas and pesticide use.

The decolonization of countries in sub-Saharan Africa between 1960 and 1980 made many of them more open to multilateral trade and assistance, so international aid agencies, along with foundations such as the Ford Foundation, the Rockefeller Foundation, the W. K. Kellogg Foundation, and the Bill and Melinda Gates Foundation, responded with substantial investments. Rural development programs in Africa have not had the same level of success enjoyed in other parts of the world. The reasons for this are the focus of scholarly debate.

DEVELOPMENT AND ETHNIC DIVERSITY
Societies that are developed afford their members a higher level of economic prosperity and political security. A key issue is whether ethnic diversity promotes or undermines the capacity to develop.

An ethnic group is a collectivity whose members believe they share a common ancestry. Many such groups speak a common language and come from a common place of origin. They tend to share a common history. The members of ethnic groups therefore often regard each other as kin, even when they cannot precisely trace the links that define their relationship. When a political entity, be it a nation or city, contains many such groups, it can be described as ethnically diverse.

In the process of development, the foundations of the economy shift from agriculture to industry. To become prosperous, individuals in developing societies therefore need to acquire new skills and to shift their place of employment. While still an active subject of investigation, research thus far suggests that ethnic groups contribute to the private welfare of individuals by assisting them in this transformation. It also suggests that at the onset of development, ethnic diversity may impede the development process, while at a later stage, it may promote it.

PRIVATE INVESTMENT
To improve the welfare of their people, ethnic groups fund schools and promote literacy. They also promote migration from country to town within a given nation and from poor countries to rich, and thus enable their members to get better jobs and to earn higher incomes. Some ethnic groups specialize in particular forms of economic activity, and therefore master skills that they then impart to kin.
By thus enhancing the prosperity of their members, ethnic groups contribute to the process of development.

ETHNIC DIVERSITY
There is some evidence that ethnic diversity enhances the impact of ethnic groups. People who live in culturally diverse cities in the United States pay higher rents, for example, suggesting that in such settings people can be more productive and thus both more willing and better able to dwell in such settings. One reason that diversity may enhance productivity may be competition among ethnic groups, which would lead to higher levels of investment in education and job skills; another may be that the special skills of one group enhance the productivity of the special skills of another. Because researchers, including Alberto Alesina and Eliana La Ferrara in 2005, report that the relationship between diversity and productivity is more pronounced in richer cities, the latter seems the more likely account.

Late-twentieth-century research has also focused on the impact of ethnic diversity on public policies, such as education, transportation, and health care. Some of these studies (Alesina et al. 1999) are based upon comparisons between urban centers in the United States; others (Miguel and Gugerty 2005), on small-scale communities in Africa. In both areas, scholars tend to find that the more ethnically diverse the political setting, the lower the quality of public services.

LEVELS OF DEVELOPMENT
That ethnic diversity inhibits the formation of public services may help to explain a major finding in this field: the negative relationship between ethnic diversity and economic growth in poor societies. First reported in William Easterly and Ross Levine's 1997 article for the Quarterly Journal of Economics, the finding has been replicated using cross-national data and data for urban areas in the United States. Since that time, however, researchers have noted that the relationship between ethnic diversity and growth is not straightforward. While negative in poor societies, it turns positive at higher levels of income, according to research by Alesina and La Ferrara (2005).

In the underdeveloped nations, economic growth may require better roads, schools, and other services, and ethnic diversity appears to make it difficult for people to cooperate in their provision. In richer economies, economic growth may be driven by the private sector, and ethnic diversity appears to enhance economic productivity.

VIOLENCE
Many argue that ethnic diversity threatens development by rendering violence more likely. This claim derives from studies of political conflicts, which often focus on the ethnic tensions that underlie them.

The claim can be challenged on several grounds. As stressed by James Fearon and David Latin (1996), the evidence is improperly drawn; societies at peace are often ethnically diverse as well. Moreover, ethnic diversity is related to poverty and poverty to political conflict; it is therefore difficult to isolate the independent contribution of ethnic diversity to political disorder. Students of Africa—the most ethnically diverse region in the world—report that it is not the diversity that promotes violence but rather concentration: when one group is big enough to capture the state, then others fear the possibility of political exclusion and political tensions therefore rise.

Ethnic groups thus energize the transformation of economies from agrarian to industrial and of societies from rural to urban; by so doing, they promote development. At low levels of income, ethnic diversity may impede development; at higher levels, it may promote it. The political dangers of ethnic diversity appear overdrawn.

DEVELOPMENT ECONOMICS

Development economics is the field of study devoted to understanding the economic experience of less-developed countries. Development economics arose during the period of European decolonization that took place immediately before and after World War II (1939–1945), as national independence movements gave rise to a large number of newly independent countries in Asia, Africa, and Latin America. While highly diverse in terms of their history, culture, climate, population size, and natural resource endowments, these countries shared a common set of economic goals, including the desire to rapidly increase their per capita incomes and reduce often widespread poverty. These desires were often linked to the related goals of rapid urbanization and industrialization that were seen as part of a larger project of modernization, and thought to be integral to national political goals including economic independence and political power on the world stage. Development economics arose as an attempt to address the economic priorities and challenges faced by these countries.

To at least some degree, the advent of development economics was a response to the perceived inadequacies of traditional economic theory as a framework for addressing the challenges posed by economic development. Traditional economics was mostly concerned with the static issue of market efficiency. In contrast, in less-developed countries, the central question was a dynamic one: how to radically transform the economy through the interlocking processes of economic growth, industrialization, and urbanization. Moreover, traditional economic analysis presumed the existence of a system of relatively well-functioning markets that simply did not exist in many developing countries. A new set of theories would be needed to understand the causes of persistent underdevelopment and suggest ways in which government policy could overcome existing market failures to speed and direct the development process.

STRUCTURALISM, DUALISM, AND DEVELOPMENT

To early development economists, the flaws in traditional economics were obvious. Less-developed countries were poorly characterized by the highly flexible national markets that typified traditional economic theory. Markets were often local and fragmentary, and individuals appeared to be more concerned with tradition and family ties than efficiency or profit. A prominent alternative was structuralism, which argued that underdeveloped markets were highly inflexible. Prices were fixed or adjusted slowly, and economic agents responded slowly to changing prices. With markets functioning poorly, the government should play an active role in directing labor and capital to their best uses.

Developing economies often appear to be “dualistic,” comprised of a modern industrial sector and a more traditional agricultural sector. The most influential model of dualistic development is due to Sir W. Arthur Lewis (1915–1991), who suggested that the traditional sector had a surplus of underutilized workers who earned a subsistence wage. This surplus labor constituted a free resource that could be used for industrialization. Workers could be withdrawn from the traditional sector without reducing the total agricultural output. The main constraint on the rate of development was a country’s ability to accumulate capital to expand the modern industrial sector.

Until it was exhausted, the surplus of labor would hold wages at a subsistence level. The gains from industrialization would go entirely to the owners of capital. Eventually, however, the expanding modern sector would exhaust the supply of surplus labor, and wages would begin to rise. Rising wages would cut into profits, slowing the rate of industrialization but also spreading its benefits to the population at large. At least initially, however, rising inequality might be an unavoidable byproduct of rapid development.

INDUSTRIALIZATION AND MARKET FAILURE

Lewis’s thinking placed industrialization at the heart of economic development. Further analysis suggested that poorly functioning markets could undermine the two processes on which industrialization relied, capital accumulation and the transfer of labor from agriculture to industry. In practice, industrial development often was accompanied by unusually high and persistent urban unemployment. John Harris and Michael Todaro (1970) suggested that this was the result of inflexible labor markets that set the modern-sector wage too high. In its simplest formulation, the Harris-Todaro model suggests that if the modern-sector wage is twice the rural wage, then each new modern-sector job will attract two rural migrants. As a result, job creation programs will actually increase urban unemployment since each new job attracts more than one rural migrant.

Markets may also fail to induce the investments in physical capital—factories, tools, and machinery—at the heart of industrialization. Many investments are profitable only if other projects are undertaken at the same time, but no one investor has the resources to finance all the relevant investments. Unless the actions of many different investors can be coordinated, none of the investments will take place. This may be the case when different investment projects are closely linked—like factories that make car bodies, tires, and glass—but the link between invest-
ments may not be so obvious. If workers at the shoe factory use their wages to purchase bicycles, and vice versa, then the profitability of investing in bicycle and shoe production will be linked.

A second problem is that financial markets and institutions may function poorly. When functioning well, banks collect savings from those with extra income and make loans to households and firms with profitable investment opportunities. In less-developed countries, this may not occur because households are geographically isolated or because it is too costly to make or collect on small loans to the poor, who often have the best investment opportunities. State-run banks may waste scarce investment resources by favoring politically powerful borrowers. Finally, some countries limit the interest rate a bank may charge. If the inflation rate is higher than the allowable interest rate, banks automatically lose money on every loan they make, resulting in financial repression.

In spite of these problems, once industrialization begins it is often self-sustaining, with the profits from initial investments providing the savings to finance additional investment. Instead of experiencing this virtuous cycle, however, many less-developed countries appeared to be caught in a poverty trap with low levels of income, profit, investment, and savings. To get the virtuous cycle started, many development economists advocated a “big push” in which the government coordinated and funded a large number of investment projects. If an underdeveloped banking system resulted in low levels of private savings, the government could finance investment through tax revenues. International aid could be used to close the financing gap if a country was too poor to finance the necessary investments on its own.

**INTERNATIONAL TRADE AND ECONOMIC DEVELOPMENT**

Skepticism regarding the role of markets in economic development was most pronounced in attitudes toward international trade. During the colonial era, many developing countries had become specialized in the production of food, minerals, and other primary products, relying on international trade for many manufactured goods. Many development economists believed this pattern of trade would make industrialization more difficult. Furthermore, the technological advantages of developed industrial countries would make it impossible for less-developed countries to compete as exporters of manufactured goods.

A highly influential version of this idea was formulated by development economists Raúl Prebisch (1901–1986) and Hans Singer (1910–2006), who argued that the price of primary products tends to fall over time relative to the price of manufactured goods. According to the Prebisch-Singer hypothesis, a developing country’s ability to industrialize would be limited by that fact that, year after year, each ton of sugar or copper or coffee exported would purchase fewer machines. These ideas led to the development of North-South trade models that examined the conditions under which trade between an industrial “North” specialized in manufactured goods and a developing “South” specialized in primary goods could lead to uneven development in which southern income is stagnant or lags northern income indefinitely. More generally, the Prebisch-Singer hypothesis furthered the argument that markets were not up to the task of guiding a country’s development.

The idea that guided developing countries’ trade policy was import-substitution industrialization. A country would industrialize by gradually replacing manufactured imports with domestically produced counterparts. Led by the infant industry argument, many developing countries adopted import quotas and import tariffs to protect domestic manufacturers until they had matured enough to compete in international markets. In the early 1960s, a few East Asian countries rejected the inward-looking policies of import substitution in favor of export promotion. Successful exporters were rewarded with subsidies, easy credit, and other forms of support.

**RADICAL PERSPECTIVES**

Market skepticism also gave rise to more radical perspectives. According to André Gunder Frank (1929–2005), the father of dependency theory, the existence of a traditional sector was evidence not of capitalism’s absence but of its fundamentally predatory nature. This is seen primarily in the tendency of capital to flow from underdeveloped rural regions to developed urban regions of a country. Center-periphery models addressed this dynamic in the international arena. Unequal exchange in international markets and the repatriation of profits by multinational firms would lead to the permanent concentration of capital in the hands of global economic elites, guaranteeing a persistent state of economic dependence for developing countries. The political domination of colonialism had been replaced by a neocolonial economic domination.

Radical economists believed that standard policy interventions were not enough to foster development. Successful development would require a fundamental restructuring of the international economic order and, often, the overthrow of the local political elite, who were viewed as the local representatives of global capital.

**THE CONTINUING DEVELOPMENT OF DEVELOPMENT ECONOMICS**

Development economics has continued to evolve since the mid-twentieth century. Development economics has
re-embraced economic theory as it has become more adept at addressing the particularities of the markets of developing countries. More importantly, economists have learned from their accumulated experience with economic development. In practice, the emphasis on industrialization often led to an "urban bias" in development, resulting in tax and trade policies that reduced incomes in rural areas where poverty was already the most severe. Early theories may also have overemphasized the role of developing-country governments, which are themselves developing and limited in their capacity for administration and oversight. Many economists point to the development success of relatively market-oriented East Asian countries and recent work emphasizing the role of corruption in continued underdevelopment. While both governments and markets are prone to fail, in developing countries the perils of government failure may well be more important.

DEVELOPMENT IN SOCIOLOGY

Development was a post–World War II concept used to describe and explain economic and social change throughout Africa, Asia, Latin America, and southeastern Europe. President Harry Truman (1884–1972) launched “the era of development” in 1949 when he committed the United States to making scientific and industrial advances available to underdeveloped areas. Four major theoretical and policy perspectives regarding development have been proposed: modernity (roughly 1940s–1950s), dependency (1960s–1970s), world systems (1980s–2000s), and market reform (1980s–2000s). Institutional, feminist, and capability perspectives also have informed development discourses. In various contexts, development has signified economic growth, income disparity, or class conflict within and between nation-states and regions of the world, and it has incorporated economic, political, and social change as well as enhanced individual freedom.

MODERNITY

Modernity theorists focused on economic growth accompanied by political stability, not on social transformation itself. They assessed economic development primarily by gross domestic product, per capita income, or extent of poverty. Political stability implied preferable but not exclusive emphasis on the development of democratic institutions. Informing the modernity school were classical evolutionary theorists, including Auguste Comte (1798–1857), Émile Durkheim (1859–1917), Herbert Spencer (1820–1903), and Ferdinand Tönnies (1855–1936), and functionalist theorists such as Talcott Parsons (1902–1979) and Edward Shils (1911–1995).

The modernity school included economists, such as Walt W. Rostow, who stressed the importance of speeding up productive investments; political scientists, including Samuel Eisenstadt and Gabriel Almond, who highlighted the need to enhance the capacity of political systems; and sociologists, such as Marion Levy and Neil Smelser, who focused on changes in Parsons’s pattern variables (a way of characterizing interactions between people) and social differentiation. Reflecting evolutionary theory, modernization was viewed as a phased process, exemplified by Rostow in The Stages of Economic Growth (1960), and as a lengthy homogenizing process, tending toward irreversible and progressive convergence among societies over long periods of time. Some have argued that modern societies had better capacity to handle national identity, legitimacy, participation, and distribution than those with traditional political systems. Reflecting functionalist theory, modernity was also treated as a systematic and pervasive process.

Early modernization theorists such as James Coleman, Rostow, and Parsons constructed ahistorical abstract typologies, viewed tradition as an obstacle to development, and neglected external factors and conflict as sources of change. In the 1980s modernity theorists such as Siu-Lun Wong, Winston Davis, and Samuel
Huntington treated tradition as an additive factor of development, conducted case studies, used historical analyses, posited multidirectional paths of development, and identified external factors and conflict as sources of development.

DEPENDENCY

Dependency theory arose in Latin America in the early 1960s, in part due to the economic stagnation associated with the United Nations Economic Commission for Latin America's policy of import substitution (producing food and raw materials for industrialized centers and, in return, receiving processed goods from these centers). Classical dependency theorists, such as Andre Gunder Frank (1929–2005), Theotonio Dos Santos (b. 1936), and Samir Amin (b. 1931), posited the bipolar theoretical construct of core (industrialized nations) versus periphery (underdeveloped nations) as an alternative to the modernists' modernity versus tradition. The historical heritage of colonialism and the perpetuation of an unequal division of international labor precluded the development of the periphery. The flow of economic surplus to European and North American developed countries kept countries in the Third World underdeveloped.

New dependency theorists and researchers of the 1970s and 1980s, such as Fernando H. Cardoso, Thomas B. Gold, Guillermo O'Donnell, and Peter Evans, viewed the nature of dependency in sociopolitical terms and as coexisting with development, rather than as mutually exclusive of it—that is, leading only to underdevelopment. They focused on historical-structural aspects of dependency, emphasizing internal aspects, class conflict, and the role of the state.

WORLD SYSTEMS

World-systems theorists, such as Andre Gunder Frank, Christopher Chase-Dunn, and Immanuel Wallerstein, made the unit of analysis the world system or, more generally, the “historical social system.” They used historical explanations from the viewpoint of the world system—the functions and interactions of all societies—and examined large-scale changes over long periods of time. As the world system expanded or contracted in its totality, that is, in terms of overall economic growth, regions and countries changed at different rates and in different directions. To account for uneven development, Wallerstein characterized capitalist world economy as exhibiting a trimodal structure of core, semi-periphery, and periphery. The addition of the semi-periphery component enabled the examination of upward mobility (a peripheral region or country moving into the semi-periphery or a semi-peripheral regional or country moving into the core) as well as downward mobility (a core region or country moving into the semi-periphery or a semi-peripheral regional or country moving into the periphery).

Alejandro Portes (1997) contends that postulating a single worldwide unit of analysis and the long-term view are major flaws of the world-systems theory. This is because most development problems, dilemmas, and decisions occur in the intermediary level of nations and communities seeking to cope with constraints in their immediate, particular situations. As a result, world-systems theorists remain outside policy debates, and their influence with sociology has been mitigated somewhat, although as So (1990) and Peet (1999) note, greater attention to microregions has much promise theoretically and practically.

MARKET REFORM

According to Portes (1997), market reform consists of seven basic steps:

1. unilateral opening to foreign trade;
2. extensive privatization of state enterprises;
3. deregulation of goods, services, and labor markets;
4. liberalization of the capital market with extensive privatization of pension funds;
5. fiscal adjustment based on a sharp reduction in public outlays;
6. downscaling state-supported social programs; and
7. an end to industrial policies and a concentration on macroeconomic management or monetary policy.

According to this model, development means success in the marketplace, with little or no attention paid to the distributive effects of aggregate economic gains either between or within countries.

Access to and integration in worldwide markets, however, is assessed by criteria that go well beyond the economic sphere. For example, the A.T. Kearney Foreign Policy globalization index, which measures the impact of globalization in sixty-two countries, comprises four dimensions of nation-state development:

1. economic integration (trade and foreign direct investment);
2. personal contact (telephone, travel, remittances, and personal transfers);
3. technological connectivity (Internet users, Internet hosts, secure servers); and
4. political engagement (international organizations, UN peacekeeping, treaties, and government transfers).
INSTITUTIONAL PERSPECTIVES
Institutional theorists, such as Nicole Woolsey Biggart and Mauro F. Guillén, propose that “development depends on successfully linking a country’s historical patterns of social organization with opportunities made available by global markets” (Biggart and Guillén 1999, p. 723). In the World Development Report 2002: Building Institutions for Markets, published in 2001, the World Bank acknowledges the importance of institutions’ mainstream approaches to development policy. The framework of Andrew Dorward et al. (2005) incorporates bottom-up, nonmarket organizations such as microfinance groups and community-property resource-management groups. Institutional change is explained in terms of the responses of powerful groups to changes in relative prices, transaction costs, and technologies. In addition to a government’s regulatory capacity, much depends on how such actors perceive possible opportunities and threats posed to their interests by alternative paths of institutional change or stagnation and their political effectiveness in influencing the paths and pace of institutional change. Change can therefore be anti-development or pro-development, with much variation within and across nations and regions throughout the world.

The approach of Dorward et al. is consistent with that of Portes (1997), who argues for a sustained systematic analysis of differing outcomes. Specifically, the analysis should require a conceptual apparatus that goes beyond the assumptions of rational self-interest and unrestricted pursuit of gain that underlie neoliberal adjustment policies. The conceptual apparatus of economic sociology, which emphasizes the embeddedness of economic action in social structures, including political and demographic factors and the roles of class and networks in guiding collective strategies, is most suited for this task.

FEMINIST PERSPECTIVES
Women in development (WID) theorists (1970s–1990s) accepted prevailing modernity theory, stressing development as a linear process of economic growth. Confined to the noneconomic domestic sphere of society, women in developing nations had been left out of the development process, according to the WID theorists. Drawing from the dependency school, women and development (WAD) theorists (1980s–1990s) argued that women have always been part of the development process and that it was this link to modernization that had impoverished them. Women were used as cheap labor for multinational corporations in export-processing zones. Gender and development (GAD) theorists (1990s) rejected the sexual division of labor as the main ordering principle of social hierarchy. Instead, race, gender, and class mattered. Unlike WID and WAD theorists, GAD theorists (1990s–2000s) treated the state as an important actor promoting women’s emancipation.

Women, environment, and development (WED) theorists (1970s) made sustainable development a central issue: They linked ideas of equity between generations, the maintenance of a balance between environmental and economic needs to conserve nonrenewable resources, and the reduction of industrialization’s waste and pollution. Postmodernism and development (PAD) theorists (1980s–2000s) did not reject theories of economic development per se, but rather favored an approach to development that accepted difference, incorporated power discourse, and fostered consultative dialogue to empower women to articulate their own needs and agenda.

CAPABILITIES
In Development as Freedom (1999), Amartya Sen conceptualizes development as a process of expanding freedoms that people enjoy. People’s capabilities underlie valuable goals of development of which measures such as gross domestic product, per capita income, industrialization, and technological advances are only indirect indicators. The notion of capabilities suggests that quality-of-life conditions must enhance the substantive freedoms that people enjoy if they are to lead the kinds of lives they have reason to value.

In Women and Human Development (2000), Martha C. Nussbaum shows how the combination of gender inequality and poverty clarifies the need for attention to capabilities. Questions about how satisfied people are with their lives or about the resources they have at hand are less important than what they are actually able to do and to be. Capabilities include being able to have good health, including reproductive health; being able to form a conception of what is good and engage in critical reflection about planning one’s life; being able to work; exercising practical reason; and entering into meaningful relationships of mutual recognition with other workers. A foremost goal of the capabilities approach is to maximize individual choice. Individuals should not be denied choice by cultures, religions, or families of which they are members, although these institutions might well provide the conditions under which individuals flourish. No institution, however, is sacred, and it is the responsibility of governments to protect individuals from any community that prohibits them from developing and exercising the basic human capacities.

Adulthood, which spans the ages eighteen to twenty-five of development for the period identified as "emerging changes since the 1980s have spurred a new conception of human development that occurs during adolescence and on into adulthood. Societal changes that occurred during the 1950s and 1960s, however, led to a critical shift in theories and research in the field of developmental psychology. With respect to adolescence, for instance, the youth movements of the 1960s brought a new interest in understanding the teenage years and led to a marked theoretical alteration in the understanding of adolescence. Before then little attention had been paid to the empirical investigation of adolescents, and the extant theories of adolescence, primarily based on clinical experiences and anecdotal reports, portrayed the teen years as a time of "storm and stress"—a time during which individuals experience severe emotional turmoil and disturbance (e.g., Hall 1904). But data collected from adolescents themselves revealed that the teen years were not as tumultuous as previously assumed and that in fact the majority of adolescents (80%) reported traversing the teen years with little turmoil, relating well to their families and peers, and being comfortable with their social and cultural values (Offer and Schonert-Reichl 1992).

THEORETICAL FRAMEWORKS
Early twenty-first century views of development examine development across the life span: the prenatal period, infancy and toddlerhood, the preschool period, middle childhood, adolescence, young adulthood, middle adulthood, and late adulthood. A life span approach to development encompasses the scientific study of human growth, change, and stability (Feldman 2006). Researchers with this perspective seek to unravel universal principles of development, characteristics, and traits that differentiate people from one another, with a focus on physical, cognitive, personality, and social development. Demographic changes since the 1980s have spurred a new conception of development for the period identified as "emerging adulthood," which spans the ages eighteen to twenty-five (Arnett 2000).
In contrast to the life span development approach, another theoretical framework for understanding development over time is the life course perspective. Life course theory emerged in the 1960s from the need to understand how individual lives are socially patterned over time and to examine the processes by which lives are changed by changing environments in which time, context, and process are an explicit part of the analysis. More specifically, life course researchers take into account both stability and change in lives as they unfold across time and generations and in historical, social, and cultural contexts.

The life course approach is an increasingly influential paradigm in social scientific thinking. In the words of Anne Colby, this theoretical approach represents “one of the most important achievements of social science in the second half of the 20th century” (Colby 1998, p. viii). One of the pioneers in this field is Glen Elder Jr., who studied children of the Great Depression, emphasizing how individual lives are socially patterned over time and the processes by which lives are changed by changing environments (Elder and Shanahan 2006).

The science of developmental psychology lacks a comprehensive and widely accepted developmental theory that unifies the field (Cole, Cole, and Lightfoot 2005). Instead, many different theories have been proposed in the study of development, demonstrating how different theories lead to different explanations of behavior across the life span. The most influential and enduring theoretical frameworks have included the psychoanalytic, learning, cognitive-developmental, and ecological systems viewpoints. Sigmund Freud was among the first to emphasize the centrality of emotional life to the formation and function of personality development (Cole, Cole, and Lightfoot 2005). His psychoanalytic theory was rooted in the idea that development moves through a series of stages in which individuals confront conflicts between their biological drives and their social expectations. Freud envisioned the immense power of the unconscious as a determinant of behavior and argued that development is largely molded by experiences in the first years of life. Although psychoanalytic theory has profoundly influenced psychology, among other fields, it is subject to criticism. Even among his own circle of disciples, Freud’s theories did not go unchallenged (Passer, Smith, Atkinson, et al. 2005). Although neoanalytic contemporaries of Freud, such as Alfred Adler, Karen Horney, Erik Erikson, and Carl Jung, agreed on the importance of both the unconscious and of childhood experiences, most argued that Freud did not give social and cultural factors sufficient importance in the role of development. Indeed because of the many criticisms leveled at Freud’s theories in terms of generalizability and testability, few present-day developmentalists are strong supporters of Freud’s theories (Shaffer, Wood, and Willoughby 2002).

In contrast to psychoanalytic theories, learning theories emphasize that development occurs as a result of behaviors learned through associations with different kinds of consequences. The most influential proponents of this perspective, John B. Watson and B. F. Skinner, argued that individuals tend to repeat behaviors that have resulted in rewards or that have allowed them to avoid unpleasant consequences. Social learning theorists such as Albert Bandura expanded upon traditional learning views to consider that a great deal of learning develops through the observation of others in the social context. Through a process known as modeling, children come to imitate behaviors they have seen others do, especially if they observe such behaviors to have positive consequences (DeHart, Sroufe, and Cooper 2004). Perhaps the greatest contribution of the learning viewpoint to understanding development has been the wealth of information gleaned through tightly controlled experiments. Learning theories are precise and testable and have helped developmentalists begin to understand why and how people form emotional attachments, adopt gender roles, make friends, and learn to abide by laws and rules (Shaffer, Wood, and Willoughby 2002). Nonetheless, the learning approach is a grossly oversimplified account of human development; it tends to overlook the contexts in which development occurs and often fails to recognize the cognitively active role that individuals play in their own development.

The cognitive-developmental perspective addresses some of these criticisms by focusing on the view that individuals actively construct a system for understanding the world rather than passively acquiring new information through simple learning mechanisms. Cognitive developmentalists seek to understand and explain the normative development of reasoning and thinking skills and argue that such skills progress through a universal sequence of invariant and qualitatively different stages. Jean Piaget is the most prominent developmental psychologist of the twentieth century, having contributed more to our understanding of cognitive development than any other scholar (Shaffer, Wood, and Willoughby 2002). Piaget’s theories legitimized the study of children’s thinking, linked moral development to cognitive development, and contributed to developmental research in social cognition—the kind of thinking that people display about the thoughts, feelings, motives, and behaviors of themselves and other people (Shaffer, Wood, and Willoughby 2002). Although critics have challenged the sequence of Piaget’s stages and recognize that he underestimated the ages at which cognitive skills develop, it is almost impossible to exaggerate the impact that Piaget’s thinking has had on developmental psychology (Beilin 1994).

A final theoretical framework is ecological systems theory, posited by Urie Bronfrenbrenner (1979). This perspective begins by assuming that natural environments
are the major source of influence on developing persons (Shaffer, Wood, and Willoughby 2002). The ecological framework views individuals in the context of all the various settings they inhabit on a daily bases (microsystems). These settings are related to one another in a variety of ways (mesosystems), which are in turn linked to settings and social institutions where an individual is not immediately present but which have an important influence on his or her development (exosystems). All of these systems are organized in terms of the culture’s dominant beliefs and ideologies (the macrosystem). Although the ecological systems perspective has gifted developmental psychology with an understanding of the complexities of the natural environment, the theory fails to explain how individuals process and learn from environmental information and is therefore not a complete account of how humans develop (Shaffer, Wood, and Willoughby 2002).

INVESTIGATIVE METHODS

Without a unified theory, how do developmental psychologists know anything about human development? Since the 1990s a variety of methods has been refined for gathering information about how development occurs (Cole, Cole, and Lightfoot 2005). Among the most widely used are naturalistic observations, survey research, and research experiments. However, no single method can answer every question about human development; each approach has its own strengths and limitations. Various approaches have a strategic role to play, dependent upon the topic under investigation and the answers being sought.

The most direct way to gather information about how development occurs is through naturalistic observation. By definition, naturalistic observation involves observing and recording behavior in naturally occurring situations without trying to manipulate the environment. Naturalistic observations allow developmentalists to observe how individuals behave in everyday life. However, such an approach is not without its limitations. For example, when people know they are being watched, they often behave differently than they normally would. In addition researchers often enter observational settings with expectations about what they are going to see and inevitably observe selectively in accordance with those expectations. Nonetheless, observational methods are a keystone of developmental research and a critical source of data about development (Cole, Cole, and Lightfoot 2005).

Researchers who opt for survey methods utilize structured questionnaire or interview techniques to ask participants questions related to such aspects of development as perceptions, feelings, or beliefs. Despite obvious shortcomings, such as attempts by respondents to present themselves in socially desirable ways, survey research is an excellent method for obtaining large amounts of information, often from a large number of participants, in relatively short periods of time.

A final investigative approach is the psychology experiment. In a true experiment the researcher controls conditions and systematically manipulates one or more variables so as to rule out all other influences on development except the one being investigated. The clear strength of the experimental method is its unique ability to isolate causal factors. That is, by controlling extraneous variables that may be influencing development, researchers can be confident that the variable of interest does indeed have an effect. A major drawback to experimental research is that the findings are not always generalizable to everyday settings, given that people do not always respond in the laboratory the way they do in the natural environment. Thus, as with the myriad of theories utilized to explain development, there are numerous approaches for investigation in the field of developmental psychology.

DEVIANCE

In *Deviant Behavior*, Erich Goode defined deviance as "behavior or characteristics that some people in a society find offensive or reprehensible and that generates—or would generate if discovered—in these people disapproval, punishment, condemnation of, or hostility toward, the actor or possessor" (1973, p. 9). While this definition of deviance is acceptable to much of the academic community, there is no consensus among academics or in the general public over what should and should not be considered deviant. Certainly, large groups of people may be able to agree on very general precepts of acceptable behavior. For example, most people in the world may agree that the killing of another person is unacceptable and therefore deviant. However, the heated debates that exist over capital punishment, abortion, stem cell research, or the permissibility of one country engaging in military action against another all highlight the difficulties in identifying something like the killing of another person as deviant. Beyond these sweeping generalities, a closer look at what is and is not permitted reveals that no act is inherently deviant. Every society has people who engage in norm-violating behavior. In fact, at some point in their lives, most people engage in deviant or criminal behavior. However, many of these rule breakers are able to avoid being formally labeled or identified as deviant because of their power or prestige, and other attributes like race or social class. Therefore, it is not the act itself that is deviant, it is how society reacts to the act that determines whether something or someone will be viewed as deviant. As Howard Becker wrote in *Outsiders*, “Deviance is not a quality of the act the person commits, but rather a consequence of the application by others of rules and sanctions to an ‘offender.’ The deviant is one to whom that label has successfully been applied; deviant behavior is behavior that people so label” (1973, p. 9).

Becker and other labeling theorists have been criticized for overstating the relativity of deviance and for failing to explain why some groups tend to be involved in more criminal and deviant behavior than others. Nonetheless, the labeling approach continues to be the dominant perspective in studies of deviance.

Cory L. Pedersen
Kimberly A. Schonert-Reichl
Many of the tenets of the labeling approach to deviance were adopted and built upon by supporters of the critical approach. Critical theorists argue that definitions of deviance intentionally favor those in positions of economic and political privilege. The political and economic elite use the law and other agencies of socialization under their control, such as the mass media, to simultaneously play up the threat of the deviant and criminal underclass while neutralizing their own law-violating and otherwise deviant behaviors. This neutralization allows the elite to profit and conduct themselves in ways that go against the best interests of society at the expense of the less powerful. Most criticisms of critical theories of deviance suggest that these theories are too vague and broad to have any practical import.

THE RELATIVITY OF DEVIANCE

The dominant belief among sociologists today is that, to a great extent, deviance is relative; what is acceptable in one place and at one time is not acceptable in a different place and time. Consistent with the labeling and critical theories, deviance is a matter of power relationships and personal and collective perspective. For example, in many contemporary societies, women who attempt to access political institutions are regarded as deviant and socially unacceptable. In all of these cases, it is men who control these institutions and therefore have the most to lose if women were to gain a political foothold. As was the case with the Taliban in Afghanistan, these men embrace norms and make rules designed to relegate women to inferior social-status positions. In contrast, formal barriers to female participation in politics are scoffed at by most people in the Western world. However, it was not until 1920 that women were guaranteed the right to vote in the United States. Only recently have surveys indicated support for a female president of the United States, and the United States still lags well behind many other nations when it comes to the number of women who hold elected government positions (Duggan 2005). Thus, while people in the United States may rightfully view Afghanistan under the Taliban as a sexist and deviant society, people in other nations where women are routinely elected to the highest political offices might think similarly of the United States.

Also, with regard to the relativity of deviance, formal distinctions between deviant and acceptable behaviors often have little to do with an objective analysis of harm or societal consensus. Rather, because of their appeal, perceived legitimacy as authorities, or control over political institutions and important resources like money and power, certain groups have a disproportionate influence over which behaviors are acceptable in a society. As sociologist John Curra writes, “Deviance, like beauty, is in the eye of the beholder, and it exists because some groups decide that other groups ought not to be doing what they are” (2000, p. 16).

Michel Foucault (1926–1984) was among the pioneers of this relativity perspective insisting that defining deviance requires the proper social perspective and an analysis of power relationships in society. In 1961 Foucault published Madness and Civilization, the results of his doctoral research—and his first major published work. In this book, Foucault examines the different ways that "madness" was perceived and addressed by those in power during the classical age (the late sixteenth century through the eighteenth century). Madness begins the era as an “undifferentiated experience,” but over the course of the classical age, due to moral and economic factors, the mad are labeled as deviant, alienated from society, and subjected to various forms of confinement by those in positions of power.

Often, certain types of behaviors are defined as deviant, not because of the will of the majority or the interests of the power elite, but because of interest groups who wish to define these behaviors as deviant because they do not fit within their value systems. In many respects, the thirteen-year prohibition of alcohol in the early twentieth-century United States resulted from the pressure exerted upon lawmakers by these “moral entrepreneurs”—people on a personal or social crusade to change attitudes toward particular behaviors. While these “reformers” were successful in formally labeling alcohol consumption as deviant behavior, large numbers of people refused to accept this label. Subsequently, a black market for alcohol emerged, leading to deaths caused by the ingestion of toxic “bootlegged” alcohol. Of even greater social consequence, Prohibition created what many historians have pinpointed as the genesis of organized crime in the United States as crime syndicates were established to meet the public demand for illegal alcohol.

In the United States, there is an ongoing crusade by moral entrepreneurs to deny gay and lesbian couples many of the basic rights and privileges that heterosexual couples take for granted. Such issues as same-sex marriage, gay couples adopting orphaned children, rights of inheritance, and coverage for domestic partners under private insurance plans are all examples of these contested issues. There have been some symbolic victories for gay couples. For example, in Lawrence v. Texas (2003), the U.S. Supreme Court declared unconstitutional laws that singled out gay couples for criminal prosecution under state sodomy laws. However, the moral entrepreneurs have gained significant ground in their efforts; many states have adopted laws prohibiting same-sex marriages and banning adoption by gay couples. As with prohibition,
only time will tell of any unintended consequences of these changes in formal conceptions of deviance.

THE DEVIANT OTHER

Traditionally, studies and theories of deviance and crime research have been primarily based on segments of the population without political and economic power, particularly racial and ethnic minorities and immigrants. Much of this research has reinforced the idea that deviance and criminality remain problems of the lower classes and people of color. Perhaps nowhere is this more evident than in deviance and drug research. While the sociological literature on drug use is extensive, the vast majority of this research explores the drug using and dealing habits of urban minorities, particularly African Americans. This is in spite of the fact that the data indicate that rates of drug use are fairly evenly distributed across race and social class, and that white people are more likely than either black people or Latinos to have used illegal drugs in their lifetime (USDHHS 2005).

A study by A. Rafik Mohamed and Erik D. Fritsvold (2006) exploring drug dealing among predominantly white college students uncovered a profitable drug network in which both the patrons and providers did not fit the stereotype of drug users and dealers. But, because of their relative affluence, race, access to costly legal counsel, and other factors related to their social status, when the illegal behaviors in this market were exposed, the dealers and users were not labeled as deviants. This study made clear that both researchers and the engineers of U.S. drug policy still do not gear drug research or drug law strategies toward people whom they resemble in social class and status. Instead, the war on drugs, like much of the research on deviant behavior in general, ignores the illicit enterprises of the affluent and continues to operate as a furtive attack against the poor and people of color.

deposits and sales independent of CSO are expected, the monopoly power of DTC will continue to decline.

Stabilization of the supply of rough and thus of prices by the CSO is accomplished in three ways: allocation of production quotas for the mines with a guaranteed minimum quota sufficient to secure continuity of production, regardless of the state of the world market; 10 yearly offerings of rough, known as “sights” to about 150 cutters and dealers in the various diamond centers; and accumulation of stocks when demand cannot sustain the prices until the market improves. The sorted and graded diamonds are placed in boxes marked with the name of the purchaser and the price. For diamonds under 14.8 carats, prices set are not negotiable. Irregular purchases may lead to exclusion from the list.

To obtain 1 carat (200 milligrams) of rough, 20 tons of rock and gravel need to be mined. Industrial diamonds, used in cutting and grinding tools, which until General Electric’s (GE) 1951 synthesis were mined as a by-product of gemstones, are no longer tied to the production of the latter. In the early twenty-first century GE and DeBeers each produced about 40 percent of industrial synthetic diamonds. Still, in some industrial cases, a preference exists for use of natural diamonds. Furthermore GE succeeded in developing synthetic gem diamonds, produced in the early twenty-first century by two companies, Gemesis and Apollo, in the United States. The industry insists that synthetic diamonds used in jewelry be promoted as such.

Diamonds show an enormous variety of shape, size, quality, and color; thus there are no set prices for diamonds, in contrast to precious metals. The industry operates then in an uninformed market in that buyers lack the knowledge of the nature of the goods they wish to purchase and therefore rely mainly on advertising as a guide, despite the existence of gemological associations that certify diamonds. DeBeers’s advertising strategy with its “a diamond is forever” ad, romanticizing and glorifying the diamond as a cultural imperative, is considered the most successful marketing campaign in history to date.

In 2000 DeBeers decided to loosen its supply control model and increase retail demand by pressuring its sight holders to engage in creative marketing. Companies began branding and patenting designer diamonds. Also vertical integration of the diamond pipeline spread in that DeBeers and independent mines sold directly to polishers and partnered with luxury retail establishments, thereby excluding middlemen.

In 2004 over 50, 25, and 15 percent of rough of 162 million carats were mined in sub-Saharan Africa, Russia, and Canada, respectively. Twenty countries produced diamonds whose value reached over $12 billion, of which Africa’s share was 60 percent. About 20 percent of the total volume was gems, and 45 percent were near gem quality. In terms of retail activity, the United States, Japan, and Europe accounted for 53, 13, and 12 percent, respectively.

The polishing of diamonds, which involves a 50 percent weight loss, constitutes an appreciable industry in several countries, of which India, with its 700,000 workers, dominates, followed by Russia, Israel, Belgium, China, and Thailand, each with thousands of employees only. The structure of the industry is highly competitive at both the polishing and the distribution levels. Concentration is much lower at the polishing end due to the prevalence of subcontracting and the absence of substantial economics of scale.

Maintenance of a distributive outlet for diamonds represents a substantial investment and requires the ability to offer a wide line of processed diamonds to potential customers. In general the greater the variety and range offered, the greater the chance of securing high margins, since the seller is able to follow changes in demand. Such higher profits can be accomplished only by large fabricators or large wholesalers who have the financial resources to stock gems whenever market conditions warrant. There is also a tendency to dispatch the polished diamonds on consignment—a practice requiring a substantial amount of working capital.

For the solely polishing centers, the volume of diamond exports should not, however, be taken as the measure of the industry’s role in the earning of foreign exchange. The value of imported rough amounts to nearly 80 percent of the value of exports, and the industry in such countries is completely dependent upon imports for its rough. The foreign currency earning rate, defined as

\[
\frac{\text{Export Value} - \text{Value Import Content}}{\text{Export Value}} \times 100
\]

ranges between 12.1 and 24.1 percent.

Ironically, while officials of DeBeers inveighed against the brutality of the South African apartheid system and even supported the emergence of black labor unions in the 1970s, the miners, separated from their families, were housed in crowded compounds with little privacy. Following legislation enacted in 2004 of the “Broad Based Black Economic Empowerment Act” passed by the South African parliament, DeBeers is to transfer for “fair market value” 26 percent of its South African diamond interests to enhance black ownership within five to ten years. Also, the company must sell a portion of its rough to a government agency, which will help expand the polishing centers in the country.

The ease with which diamonds can be transported and laundered has fueled the most vicious civil wars in Africa and has heightened Al-Qaeda’s terrorist strategies. As a result in 1998 the United Nations Security Council,

governments, and the industry enacted, with a modicum of success, anti-laundering legislation and the Kimberly Process certification system, which certifies the legitimate shipment of rough. The 2006 movie Blood Diamond is generally a correct manifestation of the cruelty pervading the diamond trade in several African countries. It illustrates the factional greed of the leaders who usurp the wealth of resources of African countries.

Of special concern to human rights groups is the employment in some countries, such as the Republic of Congo and India, of children in the mining and polishing plants despite legislation prohibiting it. Of special concern to environmental groups is the impact that open pits diamond mining has on the environment because the population is displaced to facilitate mining exploration and chemicals leach into ground water.

DIASPORA

Diaspora takes its name from the ancient Greek *dispersion*, meaning "to scatter," and, in the past, has been most closely associated with "the settling of scattered colonies of Jews outside Palestine after the Babylonian exile" (Merriam-Webster 2004, p. 345). For historians and social scientists, the concept embodies an assumption of forced dispersal, but also a shared identity organized around a mythic homeland, and the belief in a massive return (Akenson 1995, pp. 378–379). The creation of Israel, a real nation, did little to diminish this association, and the conflicts surrounding Israel’s expansion in the region still generate much discussion about the ongoing victimization of the Jewish people (Morehouse, pp. 7–8; Cohen 1997).

EXPANDING THE DIASPORA CONCEPT

The next significant groups associated with the diaspora concept are those that form the “African diaspora.” Similar to ancient and modern-day Jews, the scattering of African-descended people owes its origins to the coercive systems of colonialism, slavery, and imperialism that resulted in the forced migration of thousands of Africans to the New World, and later involuntary migration. For newly Christianized African slaves and their descendants, the story of Jewish displacement held special appeal, especially the belief in the return home. Marcus Garvey (1887–1940), founder in 1917 of the United Negro Improvement Association and African Communities League (UNIA-ACL), seized upon the diaspora desire to return home. He spearheaded a “Back-to-Africa” movement that had strong financial support, although the Black Star Line he built was intended to promote commerce between African Americans and Africa rather than return people to the land of their origins.

With such a strong symbolic connection among Christian blacks to the injustices that Jews had endured across time and space and their belief in a mythic homeland, it is not surprising that black scholars would seize upon the diaspora concept in their work. According to Brent Hayes Edwards, this concept of “diaspora” is taken up at a particular conjuncture in black scholarly discourse to do a particular kind of epistemological work” (2001, p. 46). That “work,” as described by W. E. B. Du Bois (1868–1963), was an activist-scholarly agenda aimed at bringing “intellectual understanding and co-operation among all groups of Negro descent in order to bring about at the earliest possible time the industrial and spiritual emancipation of the Negro people” (1933, p. 247).

An interest in linking the scattered population of New World people to their African homeland is central to the ideas and planning that produced the 1900 Pan-
African Congress, organized by Henry Sylvester Williams (1869–1911), and the subsequent Pan-African congresses in 1919, 1921, 1923, 1927, 1945, and 1974 organized by Du Bois and others. But most scholars studying the history of the African diaspora credit George Shepperson with joining African to diaspora (Alpers 2001, p. 4) in his 1965 paper, “The African Abroad or the African Diaspora,” for the International Congress of African Historians: Diaspora versus Migration. Seventeen years later, the organizer of the panel on which Shepperson presented his paper, Joseph Harris, would go on to edit one of the seminal texts on the topic, *Global Dimensions of the African Diaspora*. His classic definition would shape how generations of scholars interpreted the concept:

The African diaspora concept subsumes the following: the global dispersion (voluntary and involuntary) of Africans throughout history; the emergence of a cultural identity abroad based on origin and social condition; and the psychological or physical return to the homeland, Africa. Thus viewed, the African diaspora assumes the character of a dynamic, continuous, and complex phenomenon stretching across time, geography, class and gender. (Harris [1982] 1993, pp. 3–4)

**TO BE OR NOT TO BE A DIASPORA**

While the use of *diaspora* “as social form,” “as type of consciousness,” “as mode of cultural production” (Vertovec 1997, p. 277–278), as paradigm (Hamilton 1990), or as interpretive framework (Drake 1991; Gilroy 1993; Hall 1990) has grown in popularity in cultural studies, history, and the social sciences, it has also generated much controversy. Some scholars, such as Donald Akenson, argue for “a degree of skepticism” when employing the concept. He asserts that its most pristine application is to modern Jews, and anything else leads to imprecision: “That is why, were we to be master of our vocabulary, ‘diaspora’ would be a term limited only to the ancient Hebrews and their descendants, the modern Jews. To use the word ‘diaspora’ even as a metaphor for other groups is to replace a precise connotation with a fuzzy one” (Akenson 1995, p. 379). Steven Vertovec agrees, and argues that “the current over-use and under-theorization of the notion of ‘diaspora’ among academics, transnational intellectuals and ‘community leaders’ alike—which sees the term become a loose reference conflating categories such as immigrants, guest-workers, ethnic and ‘racial’ minorities, refugees, expatriates and travelers—threatens the term’s descriptive usefulness” (Vertovec 1997, p. 277).

Östen Wahlbeck counters by asserting that it is the new application of an old concept that produces new understandings of globalization and transnationalism:

In the 1990s, migration researchers have used this old concept for a variety of new purposes. Instead of studying international migration, the focus is often on transnational diasporas…. I propose that the concept of diaspora, understood as transnational social organization relating both to the country of origin and the country of exile, can give a deeper understanding of the social reality in which refugees live. (Wahlbeck 2002, pp. 221–222)

Stuart Hall offers another notion of diaspora that challenges traditional views:

Diaspora does not refer to those scattered tribes whose identity can only be secured in relation to some sacred homeland to which they must at all costs return…. The diaspora experience as I intend it here is defined, not by essence or purity, but by the recognition of a necessary heterogeneity, diversity; by a conception of ‘identity’ which lives with and through, not despite, difference; by hybridity. (Hall 1990, p. 235)

Despite these new ways of conceptualizing diaspora and the debates over the use of *diaspora* to account for so many diverse forms of movement by groups of people across time and space and for varied reasons, it remains a powerful and useful concept for history and the social sciences.

DIATHESIS-STRESS MODEL

The premise underlying the “diathesis-stress” model is that a person is more likely to suffer an illness if he or she has a particular diathesis (i.e., vulnerability or susceptibility) and is under a high level of stress. Diathesis factors that have been studied include family history of substance abuse or mental illness; individual psychological characteristics such as hostility or impulsivity; biological characteristics (e.g., cardiovascular reactivity, hypothalamic-pituitary-adrenal responsivity); and environmental characteristics such as childhood maltreatment or low socioeconomic status. Diathesis factors are generally assumed to be relatively stable but not necessarily permanent.

The term stress refers to events and experiences that may cause psychological distress. Stress can influence mechanisms that help to maintain the stability of an individual’s cognition, physiology, and emotion. Although the notion that stress can influence the development of illness has been held since the mid-nineteenth century, it was not until theories of schizophrenia proposed during the 1960s that the concepts of stress and diathesis were combined. In studies of depression that found empirical support for the model, stress has most commonly been operationalized as having experienced major negative events within the past year.

An implication of the diathesis-stress model is that the greater the vulnerability an individual has, the less stress is required for that individual to become ill. It is necessary to consider both the presence of a diathesis and a person’s level of stress in order to determine the degree of risk for the onset or reoccurrence of an illness. For example, a study of depression showed that among subjects with a diathesis in the form of genetic risk, 10 percent developed depression at low stress levels but 33 percent developed depression at high levels. For those without the diathesis, the figures were 10 percent and 17 percent, respectively.

Other health problems to which the diathesis-stress model has been widely applied include substance use, schizophrenia, and heart disease. Studies have investigated a broad range of both environmental and psychological vulnerabilities, as well as biological vulnerabilities, some of which involve genetic expression. Interest in the role of genetics in disease onset has also led to studies on gene-environment interaction, which suggest that elevation of disease risk by an environmental factor occurs primarily for individuals with a susceptible genotype.

Empirical support for the applicability of the diathesis-stress model is robust and has warranted preventive interventions targeting those at highest risk of developing negative health outcomes. For example, psychological interventions address the way a person with high vulnerability appraises and responds to stressful life events. Researchers seek to refine measures of vulnerability, provide suggestions for preventive strategies, and gather empirical evidence for the effectiveness of preventive interventions. Overall, the diathesis-stress model has provided researchers and clinicians with a framework in which knowledge about biological, environmental, and psychological processes can be used to decrease the likelihood that an illness will develop or reoccur.

Dictatorship

The concept of dictatorship originated in Rome; it was defined as rule by a leader who was selected by the Consul to govern during periods of emergency brought on by external war or internal rebellion. While legally endowed with broad powers to resolve crises, the dictator was required to step down within six months or before the end of the term of the Consul that appointed him. In addition, such exceptional power was to be used to restore the previous political order. Although dictatorial power was faithfully applied in most cases, Mark Antony (82 or 81–30 BCE) abolished the institution after both Lucius Cornelius Sulla (138–78 BCE) and Julius Caesar (100–44 BCE) used force to rule beyond their mandated terms.

The temporary nature of dictatorship was central to its conception, leading writers such as Niccolò Machiavelli (1469–1527) and Jean-Jacques Rousseau to defend its powers in responding to crises. Even rulers acknowledged the specific meaning of the term. After Napoleon Bonaparte (1769–1821) seized power extralegally, for example, he was known as “emperor,” not as “dictator.” The one exception seems to have been José Gaspar Rodríguez de Francia (1766–1840) in Paraguay, who labeled himself “the perpetual dictator”—an oxymoron by the standards of original meaning.

Even rulers acknowledged the specific meaning of the term. After Napoleon Bonaparte (1769–1821) seized power extralegally, for example, he was known as “emperor,” not as “dictator.” The one exception seems to have been José Gaspar Rodríguez de Francia (1766–1840) in Paraguay, who labeled himself “the perpetual dictator”—an oxymoron by the standards of original meaning.

The term dictatorship did not gain prominence again until the early twentieth century, when it reappeared in the guises of the self-proclaimed “dictatorship of the proletariat” in Russia and the fascist dictatorship in Italy. Both uses of the term were deviations from the original Roman conception. The fascists were never committed to any temporary notion of power. The dictatorship of the proletariat was to be temporary in nature; but as a fundamental step in the transformation from bourgeois to communist democracy, it would obviously not aim for restoration of the old order.

Attempting to retrieve the concept from communists, Carl Schmitt (1921) distinguished between commissarial and sovereign dictatorship. Commissarial dictatorship conforms to the Roman usage of the term, but is likely to give way to sovereign dictatorship that, in contrast, is unlimited and likely will establish a new order. In making such a distinction Schmitt sought to justify the extensive use of emergency powers to address social and economic crises in Weimar Germany. Still, his conception of sovereign dictatorship is important because it cements an important shift in the understanding of the term: Dictatorships need not be temporary nor restorative of the prior constitutional order.

As a consequence, the post–World War II conception of dictatorship is necessarily a broader one in which dictatorship encompasses all regimes that are not democratic. Dictatorships may be distinguished from democracies as regimes in which rulers are not governed by law (Kelsen 1945) or selected by elections (Schumpeter 1942). Still, such minimal criteria mean that dictatorships demonstrate wide heterogeneity in their organization and bases for rule.

Types of Contemporary Dictatorships

Dictatorships include both totalitarian and authoritarian regimes: The former deeply pervades society through ideological fervor, mobilization efforts, and intolerance of autonomous organization, while the latter is more pluralistic and predictable in nature (Friedrich and Brzezinski 1961, Linz 1970). Besides Nazi Germany and Joseph Stalin’s Soviet Union, however, relatively few totalitarian regimes exist. As a result, most dictatorships are authoritarian regimes, and the two terms often are used synonymously.

The most prominent distinction among contemporary dictatorships is in the location of decision-making power, which determines their bases of institutional support and their constraints. While debates abound over the exact criteria for classification, the main categories consist of military, party, monarchical, and personalist regimes.

Military dictatorships emerge by coup d’état, an extralegal seizure of power. Paul Brooker (2000) notes that the military intervention in politics may stem from “national interest” in times of crises or corporate and self-interests in the quest for greater resources. Once in power, the military consolidates both executive and legislative powers within a junta, a small collective that typically is composed of high-ranking officers. The junta is responsible for major decisions, including those governing succession. In decision making the degree of power sharing...
among service branches varies and is a common source of friction among junta members. The tension between governing and maintaining military cohesion has often led to the demise of these regimes.

In party dictatorships, power is concentrated within a single regime party that dominates political life (Huntington and Moore 1970). Other political parties may exist, but they do not pose any serious competition. Major policy decisions and issues of succession are determined by an inner sanctum of the party. Still, the party’s organizational reach is broad, pervading the armed forces and local institutions, down to the level of villages, firms, and schools. Because the party is a vehicle through which individuals may advance their careers and earn patronage, it serves as an important tool for the dictatorship in mobilizing support, collecting information, and supervising the behaviors of others. The party’s infiltration of the military also ensures civilian control over the armed forces.

Monarchies are typically treated as distinct from other forms of tyrannical rule. However, the minimalist criteria distinguishing democratic and nondemocratic regimes clearly require classifying these regimes as dictatorships. In monarchies the institution at the center of power is the dynastic family that claims historical rights to rule and monopolizes succession. The king is the effective head of government, yet as Michael Herb (1999) observes, major policy decisions and the choice of successor from within the family is determined only with the consent of other family members. Kin networks are also used to maintain control over the military and to staff government positions, ensuring the dominance of the ruling family.

Personalist regimes are those in which dictators do not overtly rely on the armed forces, a regime party, or a dynastic family to maintain their rule. As a consequence, they seemingly monopolize decision-making and conform to stereotypical notions of dictatorships as “one-man rule.” Personalist dictators may come to power via a coup or legitimate elections and are able to consolidate power by the skillful use of patronage and “charismatic authority” (following Max Weber’s notion in The Theory of Social and Economic Organization [1947]) such that they are able to avoid dependence on a single institution and hence constraints on their decision-making power.

DIET, THE

A legislature, which is the most essential political institution in modern democracies, is denoted by different terms in different countries. One such term, Diet, is the name of the national legislature of Japan. The Imperial Diet, established in 1890 by virtue of the Meiji Constitution, was the first legislature in Japan. Under the Meiji Constitution, the emperor’s prerogative was extensive, whereas the Imperial Diet functioned simply as an advisory organ to the emperor in his conduct of state affairs. The Imperial Diet consisted of two houses, the House of Peers and the House of Representatives. The former was composed of members of the imperial family, individuals who paid high taxes, and others appointed by the emperor. Members of the House of Representatives were elected by a limited franchise.

After World War II, the Imperial Diet was replaced by the National Diet under a new constitution. The Diet is now the highest organ of state power and the sole law-making entity of the state. Under the new constitution, Japan has a parliamentary system, in which the prime minister is chosen from among the Diet members by a resolution of the Diet. The Cabinet is collectively responsible to the Diet in the exercise of executive power.

The National Diet is bicameral, composed of the House of Representatives and the House of Councillors. Similar to the U.S. Congress, but different from many European legislatures, members of both houses are elected by universal adult suffrage. The electoral system in the House of Representatives is a combination of single-member districts (300 in total) and proportional representation systems (180 in total). This system was adopted in 1994, replacing the multiple-member district system. Ninety-six members of the House of Councillors are elected on the
basis of a proportional representation system, while the
remaining 146 are elected by a multiple-member prefec-
tural district system.

The constitution proclaims the superiority of the
House of Representatives with respect to budget legisla-
tion, approval of treaties, nominations for prime minister,
and other matters. If a bill is passed by the House of
Representatives but rejected by the House of Councillors,
the bill can still become law if two-thirds or more of mem-
bers support the bill in the second deliberation in the
House of Representatives.

One feature of the legislative process in the Diet is the
committee system, which is similar to that of the U.S.
Congress. When a bill is introduced in the House of
Representatives, the speaker refers it to the committee
under whose jurisdiction it falls. The deliberation in the
committee is more detailed and likely to take more time
than that in the plenary session.

Secondly, the method of interparty negotiation regard-
ing the management of Diet affairs is peculiar to Japan.
Each party represented in the Diet has its own Diet Affairs
Committee or similarly named party apparatus, and the
committee chairpersons of ruling and opposition parties
hold a conference to find a negotiated solution to an inter-
party confrontation. These conferences, which are typically
held behind closed doors, significantly influence the busi-
ness of the Diet, although the Diet Affairs Committees are
not formal organs of the Diet. This system for managing
Diet affairs is considered to be one factor that makes delib-
erations in the Diet difficult to understand.

DIFFERENCE
EQUATIONS

Difference equations or, rather, systems of these are math-
ematical models of some systems in the real world that are
believed to change their states at discrete and equidistant
points of time. An example of such a system is a univer-
sity that accepts students twice a year. The state of such a
university would be described in terms of student num-
bers—which are constant for half a year and change at two
discrete points in the course of a year (based on the num-
der of students that pass their exams and the number of
students accepted). Continuous systems, on the other
hand, change their states at any time. Systems in the real
world can usually be described in terms of both continu-
ous and discrete time. When, however, the most impor-
tant state changes occur only within a very small part of a
time span (such as within just a week per semester in a
university), difference equations are the method of choice.
The same preference applies when processes are modeled
that are only measured at regular time intervals (once a
year, once a month)—as is common, since most statistics
are only published at discrete times (even though individ-
ual events such as births, deaths, or unemployment occur
more or less continuously).

Difference equation models connect the future state
of a system to the current state or even past states of the
same system, in a way comparable to the manner in which
differential equations allow the calculation of future states
of a system from its current state. The application of dif-
ference equations supposes, however, that the processes
within the modeled system are discrete in time, whereas in
the case of differential equations processes are continuous
in time.

For a number of real systems, the use of difference
equations seems appropriate—for instance, in the case of
populations of animals with non-overlapping generations.
Here, one is only (or at least mainly) interested in the size
\( x_{t+1} \) of a given population next year when \( x_t \), the size of
the population in a given year \( t \), is known; \( x_{t+1} \) is then
expected to be some function of \( x_t \). More generally speak-
ing, \( i \) is the parameter of a process \( \{ x_t, t \in T \} \) where \( T \)
is an enumerable set, and the general form of a (first-order)
difference equation is

\[
 x_{t+1} = f(x_t).
\]

Difference equations of higher order are also possible;
a second-order difference equation has the general form

\[
 x_{t+1} = f(x_t, x_{t-1})
\]

and is often transformed into a system of difference equa-
tions, such that

\[
 x_{t+1} = f(x_t, y_t); y_{t+1} = x_t.
\]

LOGISTIC GROWTH

One of the simplest cases of a difference equation in one
variable—which also displays some interesting behavior—
is the so-called logistic or Verhulst equation, which in its
time-discrete version has the form

\[
 x_{t+1} = rx_t (1 - x_t / K).
\]
One of the interpretations of this equation is that it describes a population in a habitat with carrying capacity $K$, whose size in the next generation is proportional to a growth constant (sometimes called the Malthusian parameter) $r$, to the current population size $x_t$ and to the proportion of the habitat that, in some way, is so far unused $(1 - x_t / K)$. The equation has two stationary solutions, namely $x_{st1} = 0$ and $x_{st2} = K(r - 1)/r$. For $r \leq 1$, only $x_{st1} = 0$ is stable, and the population dies out, whereas for $1 < r < 3$, $x_{st2} = K(r - 1)/r$ is stable, and the population will stabilize at this size, and for $r \geq 3$, $x_{st2}$ is again unstable, and the system displays some interesting chaotic or fractal behavior (Schuster 1984, pp. 31–46).

AGE STRUCTURE OF A POPULATION

Another example also comes from mathematical demography, and here a system of difference equations is used to project the age distribution in a given population characterized by age-dependent death rates (which may differ between males and females) and birth rates that depend on the age of the mother. If one writes, for instance, $m_a(t)$ and $f_a(t)$ for the number of males and females, respectively, in the $a$-th year of age, and $\delta^m_a$ and $\delta^f_a$ for the age-dependent death rates of males and females, then the death part of the system of difference equations is easily formulated:

$$m_a(t + 1) = m_a(t - \delta^m_a)$$

and $f_a(t + 1) = f_a(t - \delta^f_a)$

for all $a > 1$

and for $a = 1$ the difference equation is

$$m_1(t + 1) = \gamma \sum_{a=15}^{45} \beta_a f_a(t)$$

and $f_1(t + 1) = (1 - \gamma) \sum_{a=15}^{45} \beta_a f_a(t)$

where $\gamma$ is the proportion of male births and $\beta_a$ the age-dependent fertility rate. This system of difference equations yields a series of age pyramids.

ARMA MODEL OF TIME SERIES

Time series are also often modeled with the help of difference equations. The so-called ARMA model (Box and Jenkins 1970) is of this type, where the current value of a time series is modeled as a sum of autoregressive (AR) terms and a (weighted) moving average (MA) of random shocks:

$$x_t = \alpha_1 x_{t-1} + \alpha_2 x_{t-2} + \ldots + \alpha_p x_{t-p} + \varepsilon_t + \beta_1 \varepsilon_{t-1} + \beta_2 \varepsilon_{t-2} + \ldots + \beta_q \varepsilon_{t-q},$$

where $K$ and $K'$ represent capital and capital growth respectively, and $\tau$ is the delay between the decision to invest and the realization of this decision, while $\alpha$ and $\delta$ are two parameters that weight the influence of profit and capital on the decision. Generally speaking, this model shows oscillating behavior for a wide range of values of $\alpha$, $\delta$, and $\tau$, where these oscillations can be of constant amplitude, damped or negatively damped.

As in other cases, the Kalecki equation can be rewritten into a system of difference and differential equations:

$$K(t) = \alpha / \tau K(t) - (\alpha / \tau + \delta) L(t)$$

where the first is a differential equation and the second is a difference equation. Kalecki’s approach shows that with relatively simple assumptions about the investment behavior in an economy, business cycles can be modeled. The idea is that there is always a delay between an investment decision and the realization of the capital investment, and Kalecki’s model relates business cycles to just this delay. $K$ and $K'$ are aggregated variables that in principle can be measured at very short time intervals and thus can be modeled in terms of differential equations, whereas $\tau$ is a considerably longer period of time.

DIFFERENCE PRINCIPLE

The difference principle is the second part of the second principle of John Rawls’s theory of justice. The first principle requires that citizens enjoy equal basic liberties. The first part of the second principle requires fair equality of opportunity. These rules have priority over the difference
principle; the difference principle cannot justify policies or institutions that abrogate them. The difference principle governs the distribution of income and wealth, positions of responsibility and power, and the social bases of self-respect. It holds that inequalities in the distribution of these goods are permissible only if they benefit the least well-off positions of society.

Rawls’s argument for the principle is based on the premise that citizens have, as their highest interest, two moral powers. The first power is the ability to propose and act on principles of justice all can accept. The second power is the ability to hold, revise, and pursue a conception of the good. It follows that any principle of justice, including those that regulate social and economic inequalities, must be acceptable to all and help each citizen pursue his or her conception of the good.

Rawls argues that citizens concerned to protect and exercise their moral powers would agree on principles that guarantee equal basic liberties (his first principle of justice) and the resources to pursue their good. This rules out libertarianism, perfectionism, theocracy, and utilitarianism. Citizens would not choose a rule requiring absolute equality, for everyone could do better by allowing inequalities that spur economic production. Rules that allow more inequality than the difference principle ask the worst off to accept inequalities that do not benefit them; this violates reciprocity. Moreover, citizens must have self-respect if they are to pursue their good. Self-respect depends both on having the resources to pursue one’s good and others’ recognition of one’s worth. The difference principle supports the self-respect of the worst off more than alternative principles because it maximizes their resources and expresses the commitment of the better off to share their fate. Last, Rawls argues that a principle allowing some citizens advantages that do not benefit the worst off implies that the latter are not equally worthy members of society. This endangers social stability by causing them to withdraw in sullen resentment from the public world.

Critics have charged that Rawls’s argument ignores the principle that people with greater talents deserve greater rewards than others. Rawls responds that the point of any system of cooperation citizens construct is to enable them to exercise their moral powers and pursue their good. Because citizens are equal in their moral features, they have an equal claim to the benefits from the system of cooperation. The principle of desert implies the cooperative scheme ought to reward talent rather than to respond to the essential moral features of citizens. Rawls also argues that people do not deserve their talent or the character that allows them to develop it, for they have willed neither. Last, citizens have a variety of moral, religious, and philosophical views about what constitutes desert and so could not agree on what to reward.

**DIFFERENTIAL EQUATIONS**

**Differential equations** are models of real systems that are believed to change their states continuously, or, to put it more precisely, at infinitesimally short intervals in time. Differential equations, or rather systems of differential equations, connect a change in the state of a system to its current state, or even the change in a change of the state of the same system, in a way that is comparable to the way *difference equations* allow the calculation of future states of a system from its current state. But unlike difference equations, the application of differential equations supposes that the processes within the system modeled by these equations are continuous in time, whereas with difference equations, processes are discrete in time.

For a number of real systems, the approach of differential equations seems appropriate, for instance in the case of the movement of an arrow through the air or of the local concentration of some pollutant in a lake. Here, one is only (or at least mainly) interested in the current value of some continuously measurable variable that is seen as varying continuously over time. More generally speaking, \( t \) is the parameter of a process \( \{ x(t), t \in T \} \) where \( T \) is a continuous set with the same cardinality as that of the set of real numbers; the general form of a (first-order ordinary) difference equation is

\[
\frac{dx}{dt} = \dot{x} = f(x)
\]

Here, in a more symbolic way, \( dx \) is the change that occurs to the state variable \( x \) of the system in question dur-
ing the infinitesimally short time interval $dt$ at any time $t$. Differential equations of higher order are also possible; a second-order differential equation has the general form
\[\frac{d^2 x}{dt^2} = \dot{x}^2 = f(x)\]
and is often transformed into a system of differential equations
\[
\begin{align*}
\dot{y} &= \dot{x} = f(x) = g(y) \\
y &= x = h(x)
\end{align*}
\]
Strictly speaking, in the realm of the social and economic sciences, applications of differential equations and systems of them are only approximations, because the state variables of social and economic systems cannot undergo continuous changes. In demography, for example, we can only talk about the birth and death of an integer number of people, and in economics we can only calculate with a fixed number of products sold to the customer (not even with the exception of fluid, gaseous goods, or energy, which can be physically split down to molecules and energy quanta). In social psychology, it is still an open question whether attitudes change continuously (they are usually measured on four- or seven-point scales). And even if all these variables were continuous, the question remains whether these changes occur in a continuous manner: Children are born at a certain point in time, prices are paid at a certain point in time, and until the next payment arrives in one’s bank account, the balance is constant.

On the other hand, with a large number of demographic events or financial transactions, one could argue that a differential equation is a sufficiently good approximation that is, in most cases, more easily treatable than the discrete event formalization of the real process (this even applies when the alternative is a deterministic difference equation). Differential equations can also treat probabilistic problems (then we have stochastic differential equations) and can describe processes in time and space, for instance in diffusion processes where the distribution of local concentrations or frequencies changes over time.

**UNRESTRICTED GROWTH**

Linear differential equations of the type $\dot{x} = \lambda x$ and systems of such equations can always be solved, that is, it is always possible to write down the time-dependent function that obeys the differential equation (which is the exponential function $x(t) = Ae^{\lambda t}$, where $A$ and $\lambda$ are two constants that depend on the initial condition and the proportionality constant between $\dot{x}$ and $x$ respectively). If the proportionality constant is positive, this results in an infinite growth, whereas with a negative proportionality (“the higher the value of $x$, the higher its decrease”) the value of $x$ approaches 0, though only in infinite time. This differential equation was first used in Thomas Malthus’s (1766–1834) theories of demographic and economic growth.

**ARMS RACE**

A system of linear differential equations has a vector-valued exponential function as its solution. One of the earlier applications of a very simple system of linear differential equations was Lewis Fry Richardson’s (1960) model of an arms race between two powers. The idea behind this model is that each block increases the armament budget both proportional to the current armament expenses of the other block and the budget available for other purposes. Thus, the change in the armament budget of block 1 is
\[\dot{x} = m(x_{\text{max}} - x) + ay = g + mx + ay\] with $g = mx_{\text{max}}$
The same holds for the other block:
\[\dot{y} = bx + ny = b + bx + ny\]  
The analytical solution for this system of two linear differential equations has the general form
\[q(t) = \theta_1 x_1 \exp(\lambda_1 t) + \theta_2 x_2 \exp(\lambda_2 t) + \theta_3 \]
where $q$ and $q'$ are vectors with elements $x$ and $y$ and elements $\dot{x}$ and $\dot{y}$ respectively, while $\theta_1, \theta_2, \lambda_1, \lambda_2, x_1, x_2,$ and $\theta_3$ are constants that depend on $a, b, g, h, m, n$. In a way, only $\lambda_1$ and $\lambda_2$ are of special interest, because they are—as multipliers in the arguments to the exponential functions in the analytical solution—responsible for the overall behavior of the system. They can be shown to be the eigen-values of the matrix formed of $-m, a, b,$ and $-n$, and these eigen-values can be complex, which means that besides stationary solutions, periodic solutions are also possible, at least in principle (although not in this case, where $m, a, b, h$, and $n$ are all positive). If both $\lambda_1$ and $\lambda_2$ are negative, $q(t)$ approaches $\theta_3$ as times goes by; if at least one of them is positive, $q(t)$ grows beyond all limits (which of course is impossible in the real world).

**LOGISTIC GROWTH**

One of the simplest cases of a differential equation in one variable—which also displays some interesting behavior—is the so-called logistic or Verhulst equation, which in its time-continuous version has the form
\[\dot{x} = rx(K - x)\]
One of the interpretations of this equation is that it describes a population in a habitat with carrying capacity $K$ whose size changes continuously in such a way that the relative change $\dot{x}/x$ is proportional both to the current size $x$ and to the difference between the current size and the carrying capacity ($K - x$; this difference is the proportion of the habitat that, in a way, is so far unused).

The equation has two stationary solutions, namely, $x_{\text{stationary}} = 0$ and $x_{\text{stationary}} = K$. The former is unstable: Even from the tiniest initial state, the population will grow until the carrying capacity is exactly exhausted. The time-dependent function $x(t)$, which obeys the differential equation, is a monotonically growing function whose graph is an S-
shaped curve. This time-dependent function can be written as
\[ x(t) = Kx(0) \exp(rt)/(K - x(0)[1 - \exp(rt)]) \]
This differential equation is one of the simplest nonlinear ordinary differential equations.

**THE LOTKA-VOLTERRA EQUATION**
Another well-known system of nonlinear differential equations is the so-called Lotka-Volterra equation, which describes the interaction between predators and prey. It can also be applied to the interaction between a human population (predator) and its natural resources (prey). Here, the relative growth of the prey is a sum of a (positive) constant and a negative term that is proportional to the size of the predator population, whereas the relative growth of the predator population is a sum of a (negative) constant and a positive term that is proportional to the size of the prey population. In other words, in the absence of the predator population the prey would grow infinitely, whereas in the absence of the prey, the predator population would die out.

\[ \begin{align*}
x' &= x(a - by) \\
y' &= y(-c + dx)
\end{align*} \]

This system of differential equations does not have a closed solution, but it has a number of interesting features that show up no matter how detailed the model is for the interaction between predators and prey: The solution for this system of differential equations is a periodic function with constant amplitude that depends on the initial condition. There is only one stationary state of the system, which is defined by \( y = a/b \) (this leads to \( x = 0 \)) and \( x = c/d \) (this leads to \( y = 0 \)); thus if both hold, then no change will happen to the state of the system. Otherwise the populations increase and decrease periodically without ever dying out.

**PARTIAL DIFFERENTIAL EQUATIONS**
In most applications of differential equations and their systems, the parameter variable will be time, as in the examples above. But it is also possible to treat changes both in time and space with the help of a special type of differential equation, namely, partial differential equations. They define the change of the value of some attribute at some point in space and time—for instance, the expected change \( K \) of the continuously modeled and measured attitude \( X \) of a person that has the value \( x \) at time \( t \), where this change will be different for different \( x \) and perhaps also for different \( t \)—in terms of this point in time and space. Thus,

\[ K(x, t) = \frac{dx}{dt} = \partial V(x, \partial)/\partial x \]

For an application, see the next paragraph. Partial differential equations are seldom used in the social sciences because, typically, continuous properties of individual human beings—if they exist at all in the focus of interest of social scientists and economists—are difficult to measure, and even more difficult to measure within time intervals that are short enough to estimate any parameters of functions such as \( K \) and \( V \) in the above equation.

**STOCHASTIC DIFFERENTIAL EQUATIONS**
Stochastic influences can also be inserted into the formulation of differential equations. The simplest case is the so-called Langevin equation, which describes the motion of a system in its state space when there is both a potential whose gradient it follows and some stochastic influence that prevents the system from following the gradient of this potential in a precise manner. This type of description can, for instance, be used to describe the attitudes of voters during an election campaign. Each voter's attitude can be defined (and measured) in a continuous attitude space. Their motions through this attitude space (say, from left to right; see, e.g., Downs 1957, p. 117) are determined by a "potential" that is determined either by some parties that "attract" voters toward their own positions in the same attitude space or by the "political climate" defined by the frequency distribution over the attitude space. In the latter case, voters would give up their attitude if it is shared by only a few and change it into an attitude that is more frequent. Thus they follow a gradient toward more frequent attitudes; but while moving through the attitude space, they would also perform random changes in their attitudes, thus not obeying exactly the overall political climate. And by changing individual attitudes, the overall "climate" or potential is changed. The movement could be described as follows:

\[ q(t) = -\gamma \partial V(q, \partial)/\partial q + \varepsilon, \]

where

\[ V(q, \partial) = -\ln f(q, \partial) \]

and \( f(q, \partial) \) is the frequency distributions of voters over the attitude space at time \( t \) (\( V \) would be a polynomial up to some even order in \( q \)). One would typically find voters more or less normally distributed at the beginning of an election campaign, but the process described here would explain why and how polarization—a bimodal or multimodal frequency distribution—could occur toward the election date (Trotzsch 1990).

DIGITAL DIVIDE

The digital divide has been conceived as the lack of access to information and communication technologies among underrepresented ethnic minorities, those of lower socioeconomic levels, and people living in rural locales. Several studies have characterized these disparities along dimensions of gender (Kvasny 2003), age (Loges and Jung 2001), race (Hoffman 1999, Kvasny 2003, Payton 2001), geographical location (Sipior et al. 2004), and educational resource characteristics (NTIA 2000, Payton 2001, Kvasny and Payton 2005). Karen Mossberger and Caroline Tolbert (2003) have found that African Americans are less likely to have access to information and communication technologies and the skills to use such technologies, even when controlling for other factors, such as income and education. Similar findings have been documented for Hispanic and Native Americans. Despite these foundations of physical access, the digital divide concept is not limited to a binary taxonomy of access versus nonaccess, or the typical classification of “have” and “have not.” In fact, the digital divide warrants a broader definition—one that is inclusive of social, economic, and technology-use attributes—which can capture the notion of digital equity. This concept rests on critical issues of how individuals can use information provided by these technologies and what strategic skills are desirable to prosper in the competitive environment of today’s global information age.

WHAT IS DIGITAL EQUITY?

Digital equity raises issues of social justice and can be defined as a trend toward equal access to information and communication technologies among society’s citizens. Even more, digital equity enables individuals to gain knowledge and skills to use technological tools, computers, and the Internet (i.e., behavioral outcomes). The National Institute for Community Innovations reports that:

According to recent research by the National Center for Educational Statistics, 98% of schools and 77% of instructional rooms have computers and are connected to the Internet. But many classrooms and important educational projects are not connected, and these educators are deprived of excellent Internet-based resources. Most important, even though a school or classroom may be connected, the technology may not [be] used by students—leaving many young people technology-illiterate, without key skills they need to succeed in today’s job market. (National Institute for Community Innovations 2005)

Similarly, Austan Goolsbee and Jonathan Guryan reported that California’s public schools were funded by nearly $937 million for a program known as E-Rate (education rate) during the 1998 to 2000 school years, of which a substantial portion provided Internet access and technologies. This program noticeably closed the digital divide for Internet access between wealthy and poor California schools. If one assesses effectiveness in terms of access, the California E-Rate initiative has been successful. Goolsbee and Guryan note, however, that despite this accomplishment, Internet access did little in the way of improving student performance; they conclude that “the Internet itself . . . seems unlikely to be a silver bullet for solving the problems of America’s public schools” (2006, p. 65).

OTHER CONSIDERATIONS

In its 2003 fiscal budget, the administration of President George W. Bush reduced funding for community-based technology-related programs and training initiatives by $100 million, as shown in Figure 1.

Much of this funding previously supported underrepresented minorities, children, and rural programs. While the digital divide is an immediate and direct effect of the eradication of these training initiatives, the more dire consequences rest in the lack of social justice produced by such digital inequities. Evidence of these outcomes has been documented by the National Telecommunications and Information Administration (NTIA) report “A Nation Online: How Americans Are Expanding Their Use of the Internet” (2002). The NTIA reports that individuals benefit from being prepared with technology skills, and 57 percent of employed Americans over the age of twenty-five use a computer in the workplace. By 2010 jobs in science, technology, engineering, and mathematics
are expected to increase by 67 percent according to the U.S. Department of Labor as reported in the 2002 CyberEducation Report by the American Electronics Association. In addition, the costs associated with broadband access to the Internet heighten digital exclusion and often preclude minority, low-income, rural, and undereducated populations from access to the social justice associated with social, community, economic, and education capital foundations.

Unlike other forms of communication media (e.g., radio, television, and printed materials), the Internet is distinctive because of its integration among diverse communication modalities, such as broadcasting, reciprocal interaction, group discussion, person-machine interaction, and reference research (DiMaggio et al. 2001). The digital equity principle examines how Internet access is used, and evidence supports the argument that parity is achievable when all populations gain the knowledge and skills to impact social inclusion—thereby stimulating social justice. The most noteworthy form of inclusion would necessitate equalities (therefore reducing or eliminating disparities) in education, health care, and economic and financial systems.

The digital divide or inequity issue is not limited to the United States. According to statistics from the World Summit on the Information Society, a comparison of Internet access and use in eight industrialized nations (Canada, France, Germany, Italy, Japan, Russia, the United Kingdom, and the United States) compared to the rest of the world indicates that: (1) In 2004 fewer than three out of every one hundred Africans used the Internet, compared with an average of one out of every two inhabitants of the industrialized countries; (2) the eight industrialized countries are home to just 15 percent of the world’s population but almost 50 percent of the world’s total Internet users; and (3) there are more than eight times as many Internet users in the United States than on the entire African continent. Sundeep Sahay and Chrisanthi Avgerou concluded that information and communication technologies are key to the development of poorer nations and offer the “potential for turning around uncompetitive industries and dysfunctional public administration, and for providing unprecedented opportunities for the information-intensive social services, such as health and education” (2002, p. 73).

DIOP, CHEIKH ANTA
1923–1986

Cheikh Anta Diop was the most daring African cultural-nationalist historian, scientist, and nonapologetic Egyptologist of the twentieth century. His scholarship on the reclaiming of black civilization produced an immense body of knowledge on ancient Egyptian civilization. His argument that ancient Egypt was essentially Negroid and that the origins of Hellenic civilization were to be found in black Africa challenged the prevailing Eurocentric view of the world.

The implications of Diop’s thought should be contextualized within the European imperialist dictum and black resistance movements of the time. He grew up in Senegal when France was consolidating its colonial rule in Africa, and he lived through the consequences of increasing neocolonialism, economic reforms, and militarization in Africa. Born in a Muslim family on December 29, 1923, in Caytu, a small village near the town of Diourbel, Senegal, Diop attended the local Koranic school before enrolling in a French colonial school. In 1945 his interest in science and philosophy was consolidated when he earned his baccalaureate in mathematics and philosophy in Dakar, Senegal. Diop left Senegal for France in 1946. He pursued graduate studies in France, and elected courses in science while studying philosophy under Gaston Bachelard (1884–1962) at the Sorbonne in Paris, where he earned a degree in philosophy in 1948. In 1950 Diop was awarded a certificate in general chemistry and another in applied chemistry. He studied nuclear physics at the nuclear chemistry laboratory of the Collège de France under the supervision of Frédéric Joliot-Curie (1900–1958) and at the Institut Pierre and Marie Curie. On January 9, 1960, Diop successfully defended his doctoral dissertation: “L’Afrique noire précoloniale et l’unité culturelle de l’Afrique noire” (Precolonial Black Africa and the Cultural Unity of Black Africa).

Back in Senegal, Diop continued his studies on culture, history, and linguistics. He also became involved in politics and established an opposition party, the Rassemblement National Démocratique (National Democratic Rally), having earlier served as secretary-general of the students’ unit of the Rassemblement Démocratique Africain. Appointed assistant with teaching duties at the Institut Fondamental d’Afrique Noire of the University of Dakar, he became director of the university’s radiocarbon laboratory. In 1981 Abdou Diouf, president of Senegal from 1981 to 2000, appointed Diop professor in the department of history. Diop passed away in Dakar on February 7, 1986. The university and the street in front of it were later named after him.

Diop received a number of awards, including the prestigious African World Festival of Arts and Culture Prize for scholars who had “exerted the greatest influence on African peoples in the 20th century,” which he won jointly with W. E. B. Du Bois (1868–1963) in 1966 (a posthumous award for Du Bois). Diop was also awarded the Gold Medal for African scientific research and the African Grand Prize of Merit from the National University of Zaire in 1980.

The journal and publishing house Présence Africaine, founded by Alioune Diop (1910–1980) in 1947 in Paris, published most of Cheikh Anta Diop’s classic works. These two were not related, but they were both from the Lebu ethnic group that speaks the Wolof language. Diop’s important publications include: Nations nègres et culture (Negro Nations and Culture, 1955); L’unité culturelle de l’Afrique noire (The Cultural Unity of Black Africa, 1959); Antériorité des civilisations nègres: Mythe ou réalité (The African Origin of Civilization: Myth or Reality, 1967); Physique nucléaire et chronologie absolue (Nuclear Physics and Absolute Chronology, 1974); and Les fondements économiques et culturels d’un état fédéral d’Afrique noire (The Economic and Cultural Foundations of a Federated State of Black Africa, 1974). In 1981, he pub-
lished Civilisation ou barbarie: Anthropologie sans complaisance (Civilization or Barbarism: Anthropology without Complacency), a masterpiece on ancient Kemet (Egypt) and its influence on the Greek and Roman worlds. In 1991 this title was translated and published as Civilization or Barbarism: An Authentic Anthropology.

Diop took Africa seriously, and set it against the artificiality of colonialism. He was never a Marxist or a Pan-Africanist like Ghanaian statesman Kwame Nkrumah (1909–1972), but a nationalist who emphasized the value of historical consciousness as an ideological foundation for building black federalism. His views on development included Africa's acquisition of nuclear capabilities, industrialization, self-determination, and self-reliance.

Married to a white French woman (Marie-Louise) who was an important supporter of his scholarship, Diop abhorred racism. He was also critical of sexism, which he considered a product of foreign influences in Africa. He was, however, accused of being reductionist or essentialist because he insisted on a corrective scholarship. He never argued that black Africans were monolithic and genetically superior to other races. But based on his research on the Nile Valley region and West Africa, he concluded that the ancient Egyptians were bioculturally black. Diop was convinced that the history of Africa would remain in suspension and could not be written correctly until African historians connected it to the history of ancient Egypt. However, despite cultural similarities and historical connections between various layers of African civilizations from the ancient period to the present, Diop did not prove how the study of Kemet semantics could be effectively used to examine the importance of the orality of African traditions. It is unclear how the particularities of other African civilizations fit into Diop's grand paradigm.

Diop's views have been revisited in various forms through the rise of Pan-African discourse in institutions of research and higher learning in Africa and among the African diaspora, especially in Brazil, the United States, and France. Furthermore, the promotion of scholarship on the African renaissance, both as a political concept articulated by well-known African political figures and the African Union and as an analytical and intellectual tool used by scholars to understand Africa, has also contributed to the reification of Diop. Because of the serious and degrading socioeconomic and political conditions that paralyzed most African institutions and societies and demotivated researchers during and after the cold war, there has been an intellectual movement to investigate Diop's sources, hypotheses, and arguments as part of a broader search for African solutions to global malaise. For instance, the promotion of indigenous knowledge systems as a new area of study in some African universities and research centers was inspired by Diop's claims concerning the role of culture, history, linguistics, and science in socioeconomic and political progress. In some parts of the African diaspora, this movement has led, contrary to Diop's intellectual convictions, to the development of a cult of personality. Some have also begun to view as religious or mystical Diop's teachings on the role of science in finding truth and the utilization of these truths as the basis for social progress. Diop himself, however, attempted in his works to separate sentiment and emotion from scientific logic, principles, and objectivity.

In his final book, Civilisation ou barbarie, which is considered his magnum opus, Diop expanded on, clarified, and synthesized his arguments from L'Afrique noire pré-coloniale (Precolonial Black Africa, 1960) and Antériorité des civilisations nègres: Mythe ou réalité (The African Origin of Civilization: Myth or Reality, 1967). He emphasized the primacy of African culture by proving that ancient Egypt was a black society both in its historicity and in its cultural achievements, later claimed by Indo-Aryan cultures. He strongly denounced the falsification of modern history as a major part of an agenda that has slowed world progress. Furthermore, he argued (more like an ethicist than a scientist) that humanity must break definitively from racism, genocide, and slavery and that such efforts should form the ultimate mission of the world in order to build a global civilization and avoid falling into barbarism. Diop believed in the need for a new ethics that could take into account scientific knowledge, which uniquely differentiates "modern" humans from "primitive" people. For Diop, science is a liberating, moralizing, and progress-oriented force; scientific studies on the centrality of the historicity of Africa and its contributions could humanize the world.

There are disagreements among scholars about how specifically Diop's thought has inspired generations of African Americans, both academics and community leaders, and their institutions. Certainly his intellectual impact on them cannot be denied. For Diop, learning the true history of Africa, and of the world for that matter, is essentially a scientific endeavor. In most of his works, he insisted that such a science requires first the utilization of objective methods through which empirical facts can be tested. This position may not distinguish him from other scientists, but the establishment of Africa as the birthplace of the human family is a unique knowledge that has been used differently by various cultures and peoples. For instance, one of the epistemological bases of his disagreement with Senegalese president Léopold Sédar Senghor (1906–2001), a cofounder of the Négritude movement and a member of the French Academy, was Diop's view that Senghor was making historical claims about black cultures on the basis of speculation, imagination, and sentiment and not on scientific grounds. Diop tried to make clear distinctions between science and belief systems or
Diplomacy

ideology. For Diop, ideology played an important role only in instrumentalizing science. He believed that the use of truth could make the world better. Diop’s science can be used to actualize a worldview, an ideological position of humanizing the world. His perspectives tended to privilege social applications of science.

Diop’s thought inspired two main groups of American Afrocentrists: those who used Afrocentricity as an interdisciplinary research method with a focus on African history and culture in the academy, and those who used Diop’s racial centrality as an ideology of social reconstruction in the struggle for change in society at large. In the academy, Diop’s work was consolidated with the expansion of black, Afro American, or Africana studies in the United States, where African Americans had been searching for an African cultural identity. However, with the rise of neo-integrationism in the United States and its tendency, with the support of opportunistic black scholars, to weaken “ethnicity” or “race,” Diop’s quest for Negroism has been marginalized and even trivialized in some institutions. In major American research universities, for instance, as they attempt to meet the rising demand for multiculturalism and diversity, his scholarship is perceived as advancing particularism and separatism. Clearly, these new perspectives are ideological, rather than scientific, constructs. Thus they are strongly supported and promoted by neoconservative university and college administrators with the collaboration of some African American and African academics. Diop’s scholarship embodies a defensive epistemology, rejects a myopic determinism, and emphasizes the black cultural renaissance.

Based on Diop’s impressive multidisciplinary training, his research, and his philosophical claims on pluralistic methodologies, he is known as an anthropologist, Egyptologist, historian, linguist, mathematician, and physicist. However, his all-embracing disciplinary approach produced, at best, eclectic and binary analytical and intellectual perspectives (black-based paradigms versus white-based paradigms). These perspectives are difficult to assess clearly in terms of their effective collective quality and their impact on the study of specific African cultures and histories, especially those that developed independently of or parallel to the ancient Egyptian civilization. Diop has been much criticized for being a jack-of-all-trades and a master of none. His generalizations about African languages and their connection to ancient Egyptian languages through Wolof, a Senegalese language, were essentially deductive, imaginative, and ahistorical. However, despite controversial hypotheses and conclusions associated with his interdisciplinary methodologies, Diop produced an important and unified referential body of knowledge on Egypto-centrism. His thought is philosophically complex and intellectually challenging, and it embodies an interactive methodological inquiry. Diop’s work cannot be fully translated into a single mode of thinking and doing, as reflected in certain affirmative dimensions of much-simplified American Afrocentricity.

DIPLOMACY

Diplomacy is often simply referred to as the dialogue among nations, but it is more precisely a dialogue among agents of nations, or diplomats. The word diplomacy originated from diploma, which in early modern Europe was the letter of credence that certified an ambassador’s power to negotiate and serve as the direct representative or plenipotentiary of the sovereign.

DEFINING DIPLOMACY

Diplomacy is a central concept in the study of international relations, although scholars often disagree about its function. There is a general distinction in the social science literature between diplomacy as foreign policy, and diplomacy as the process of negotiation and deliberation that promotes peace and cooperation among nations. Diplomacy as foreign policy is the expressed desire of nations to use words before force. It is the default mode of operation for liberal states, and it is often the aim among nonliberal states to engage in diplomacy if they seek acceptance in international politics. Among early political scientists, the word diplomacy was used interchangeably with international relations. In the twenty-first century diplomacy often takes the form of membership in international organizations such as the United Nations (UN), the North Atlantic Treaty Organization (NATO), and the World Trade Organization (WTO).

However, diplomacy as simply foreign policy captures only a superficial element of the workings of international relations. Diplomacy encompasses a great number of international activities that do not include processes of cooperation. As José Calvet de Magalhães points out in The Pure Concept of Diplomacy (1988), states can engage in unilateral contact such as propaganda, espionage, and
political or economic intervention. They can also engage in violent contact such as threat, deterrence, and economic war. Thus, the definition of diplomacy as a dialogue among nations is very broad.

Diplomacy as a process of negotiation and deliberation highlights the fact that the "art of diplomacy" is a skill that certain individuals, called diplomats, possess. Thus, diplomacy is defined specifically as an act of negotiation among accredited persons, not nations as a whole. Social scientific approaches that regard nations as unitary actors ignore the important subtleties of the art of negotiation that can often make or break efforts to reach compromise. Diplomats are people with individual and collective agency who interact over time and who are the products of a rich historical tradition of norms, negotiation, and representation. In political science there are two main approaches to understanding the work of diplomats or the process of diplomacy. One is that negotiations are conducted as hard-bargaining scenarios, and the second is that shared norms among diplomats can result in persuasion and informal methods of compromise.

THE STUDY OF DIPLOMACY

The first approach, bargaining theory, predicts that diplomats are important to outcomes of international cooperation because they reduce “transaction costs” in negotiations among nations. Transaction costs consist of the expense and inefficiency that would be involved in international cooperation if statespeople, as nonexpert negotiators, were to conduct all foreign policy on their own. Robert Putnam (1988) is well known for his argument about two-level games among diplomats. In his model level 1 is the negotiation phase, where diplomats bargain at the international table. Level 2 consists of the ratification stage in which there are separate discussions within each group of constituents about whether to ratify the agreement. For Putnam, there is a “win-set” that represents all the possible level 1 agreements that would “satisfy” level 2 constituencies. The size of the win-set depends on the distribution of power, preferences, and possible coalitions among level 1 constituents.

Many scholars argue that bargaining theory tends to be overdeterministic and advances a snapshot view. The methodology of comparing initial state preferences to final outcomes misses the critical processes that occur in-between. By ignoring factors such as relationships among negotiators, professional background, expertise, and shared normative frameworks, bargaining theorists pass up explanatory power.

The second approach argues that persuasion and informal methods of reaching compromise occur because diplomats come to share norms as they interact over time. For example, who the diplomats are, whether they have interacted on prior occasions, what kind of training they have received, how they were selected, their skill level, and so on are all important. In effect, diplomats cultivate relationships with one another throughout their careers, giving them a fundamental basis of interaction or shared understandings about the way international relations should work. Naturally, relationship building is often strongest among diplomats who work in international organizations. Thus, they are more likely to reach cooperative outcomes through persuasion and informal means than hard-bargaining approaches would anticipate. Of course, the power and resources of each state have some bearing on the leverage diplomats have in negotiation, but outcomes still rest on the abilities of individual diplomats and on their dynamic as a collective. Robert Jervis argues in Perception and Misperception in International Politics (1976) that perceptions of power, not actual power, are the key to any form of international relations whether in war or peace. Diplomats may often contribute to such perceptions.

Relative power among nations may play a role in determining whether or not state leaders decide to try to cooperate, but persuasion is to a significant extent out of the grasp of power. The ability to persuade is often in the hands of the diplomats. This was evident in the mammoth efforts of Secretary of State Colin Powell in 2002–2003 to sell the policies of the Bush administration—often relying more on the perception of his own independence and public respect to bring some credibility to a policy that was otherwise resisted. This occurred perhaps most notably in the UN Security Council debates over the possibility of going to war in Iraq, where some distancing by Powell made him more credible in the assurances he gave.

Despite the many ways in which diplomacy may smooth the interaction among nations, either through hard bargaining or persuasion, diplomacy does not always pay off. A compromise solution may seem continuously out of reach, such as in the relationships between Israel and the Palestinians, India and Pakistan, and nations such as Iran and North Korea with the rest of the world. Sometimes historical, religious, cultural, and political differences within nations may be so strong that even diplomacy may have a hard time providing a solution.

DIRECT ACTION

Direct action is a method and a theory of confronting objectionable practices and/or effecting social change using readily available means. Such action is usually contrasted with indirect forms of social and political participation such as voting. Protest demonstrations, mass rallies, strikes, boycotts, workplace occupations, and riots constitute examples of such action.

The first mention of the term is in the realm of labor struggles. In his book Direct Action (1920), William Mellor defined direct action as "the use of some form of economic power for the securing of ends desired by those who possess that power" (p. 15). Mellor considered direct action a tool of both employers and workers. Accordingly, he included within his definition lockouts as well as strikes. Since the late twentieth century, however, direct action has come to be increasingly associated with challenges to established societal practices and institutions by marginalized groups.

The power of direct action depends largely on its contentiousness, or the extent to which it bypasses or violates the routine conflict resolution procedures of a political system. Whereas such action can be used by recognized actors employing well-established means of claim making, substantial short-term political and social change more often emerges from the congruence of newly self-identified political actors with innovative forms of claim making. Most campaigns for social change—notably those seeking to expand the suffrage, protect civil rights, and improve working and living conditions—employ direct action repertoires.

Direct action outside of the political process is usually juxtaposed to institutionalized, routine, and/or regularized forms of social and political participation. Accordingly, one of the most commonly drawn distinctions is whether such action is carried out in a peaceful or forceful manner. Violent direct action, it is often assumed, is more contentious than nonviolent direct action because the former exhibits a high threshold of social transaction costs. Nonviolent direct action, on the other hand, has proved effective in highly repressive settings due to its unpredictability and transformative power.

Nonviolent direct action has been developed into a theory of civil disobedience by civil movements around the world. Pioneered by the American author Henry David Thoreau in his 1849 essay Civil Disobedience, it encompasses the active refusal to obey the laws of a government or an occupying power without resorting to physical violence. It has been used effectively by nonviolent resistance movements in the fight for independence in India, in South Africa in the fight against apartheid, and by the civil rights movement in the United States.

The mechanisms that make direct action contentious are then complex. First, there are social actors who are limited in the forms of action that are available to them, and expressions of discontent that are strictly bound to specific social or economic groups. Secondly, the political opportunities that countries make available and the resources that citizens bring to bear on this form of politics vary greatly around the world.

As of 2005, more than half of the world’s nations held regular multiparty elections, more than at any time in history. As societies democratize, political opportunities increase, making direct action more routine. With the spread of democratization, some have argued, the protest demonstration has become a modular form of direct action available to multiple groups.

DIRIGISTE

The counterpart to the economic doctrine of laissez-faire, dirimsme refers to an economic system dominated by state control of the market economy. Technically, the concept...
does not refer to the centrally planned economies of the former Soviet bloc, but to basically capitalistic economies that have extensive regulations and controls throughout that impact production and consumption. Many of the controls are justified because they curb productive inefficiencies, others because they correct market inequities, and still others because they protect consumers from faulty products or their own faulty decisions. In short, dirigisme describes an economic system in which the government is omnipresent and assumed to be omnipotent.

Most modern economies operate to some degree dirigistically. Government regulation and control are a significant part of most economies throughout the world today. But a significant amount of evidence has been amassed that demonstrates that economic freedom rather than government control is positively correlated with economic growth (Gwartney and Lawson 2006). In this work motivated by Milton Friedman’s *Capitalism and Freedom* (1962) and *Free to Choose* (1980), economic freedom in a country is determined on the basis of an analysis of the security of private property and the freedom of contract, the tax burden, the inflation rate, the extent of regulation, and the prevailing policies toward foreign trade. When property rights are weak, taxes are high, inflation is ramped, regulation is extensive, and protectionism rather than free trade defines the policy space, the economic freedom score will be low. See Figure 1.

A key issue to remember in debating the role of government in an economic system is to distinguish between scale and scope. Much of the debate over “big government” focuses on the issue of scale—government spending as a percentage of gross domestic product. But in debating the impact of dirigisme, it may be more appropriate to focus on the issue of scope—the extent of activities the public sector attempts to control in economic decision making. A “big government” that permits a wide range of economic freedom would be less cumbersome on economic life than a “small government” that tries to control prices in every sector. The lack of economic freedom, not the size of government, causes the decline in economic growth in nations. See Figure 2.

In many ways, these various indices of economic freedom and the empirical relationship to the economic performance of countries is capturing Adam Smith’s wisdom with the modern tools of economic analysis. As Smith put it in the notebooks that were the basis of *An Inquiry into the Nature and Causes of the Wealth of Nations*:

Little else is requisite to carry a state to the highest degree of opulence from the lowest barbarism, but peace, easy taxes, and a tolerable administration of justice; all the rest being brought about by the natural course of things. All governments which thwart this natural course, which force things into another channel or which endeavor to arrest this progress of society at a particular point, are unnatural, and to support themselves are obliged to be oppressive and tyrannical. (Smith 1776, p. xliii)

Thus, the proper scope of government in relationship to the economy is a vital question to address in assessing dirigisme as an economic policy regime.

This is not to say that questions of scale do not matter—they clearly do. James Buchanan, who was awarded the Nobel Prize in 1986, would often ask his students whether a fly that grew to nine times its current size could
still fly. He was raising the question of "dimensions" to get to the question of "fiscal dimension"—could a government grow to nine times its current size and still function? But Buchanan also raised questions concerning the scope of government.

In *The Limits of Liberty* (1975) he put the puzzle of political economy in the following manner. He first divided the activities of the state by functions: the protective state, the productive state, and the redistributive state. The protective state refers to the government provision of law and order domestically and defense against international aggression. The productive state refers to either the production or provision of certain public goods that are essential to the development of a prosperous social order. The redistributive state refers to those set of government activities that attempt to reallocate resources from unfavored groups to those groups that are more in favor. Buchanan’s puzzle is in how to empower the productive and protective state without unleashing the redistributive state. This is a question of constitutionally curbing the scope of governmental activities so that the positive-sum games of economic processes are not undermined by the zero-sum and negative-sum games of redistributive politics.

Dirigisme, in contrast, rejects as old-fashioned any concern among economists with questions of either the scale or scope of government. Instead of curbing government, the social philosophic mindset is to enlist the state to curb the excesses of the profit motive and individual myopia. In French political and economic history dirigisme is associated with Charles de Gaulle and was represented as an alternative to the Soviet model of a command economy and the U.S. model of a laissez-faire economy. When François Mitterrand came to power in 1981 he promised to move the French economy further in the socialist direction by nationalizing firms and banks, but by the mid-1980s he was forced to reverse this policy path due to declining economic performance of the French economy, and dirigisme was rejected (though the remnants of the past policies were certainly not eliminated).

The doctrine of state control of the economy runs into problems of a theoretical and empirical nature. First, empirically, as mentioned above, economic freedom is positively correlated with economic growth, whereas economic control is correlated with economic stagnation. Economic controls thwart innovation, distort the pattern of resource use, and frustrate consumers by offering them a choice of expensive but low-quality products and altogether eliminating from the market the goods they want to secure. Second, the empirical reality of productive inefficiency and consumer frustration follows directly from the persistent and consistent application of the economic way of thinking to questions of the operation of dirigisme.

There are five problems with government attempts to control a market economy:

1. incentive incompatibility—where government controls ask individuals to act in ways that violate their self-interest;
2. distortions in the structure of prices—where government controls result in price signals that lead to malcoordination of economic activities;
3. time inconsistency—where government action at time T1 is inconsistent with the government action required at T2;
4. dynamic instability—where government action results in consequences that are unacceptable from the point of view of the policy maker and thus require adjustment to either more extensive controls or abandonment of the policy altogether; and
5. rent seeking and capture by special interests—where the very existence of government action sets in motion a zero-sum game of privilege-seeking by special interests to cause the government to rule in their favor.

According to arguments 1 through 4, government controls result in unintended consequences; according to argument 5, the undesirable consequences are the result of the logic of concentrated benefits and dispersed costs. These unintended consequences are undesirable because they are wealth-destroying rather than wealth-creating. Dirigisme is an unworkable public policy philosophy.

DIRTY FLOAT

Dirty float is a term used in international economics to describe a specific policy of a country's monetary authority with respect to control over movements in the value of the nation's currency within the foreign-exchange market. Specifically, a dirty float, also known as a managed float, is a type of exchange-rate regime, or policy, in which the government or the central bank of the country occasionally intervenes in the foreign-exchange market in order to affect the exchange rate. The term is coined as a counterpart to the clean, or free, float, under which the government never intervenes in the foreign-exchange market. Both clean and dirty floats represent the floating exchange-rate regime, under which the government does not commit to maintain a specific level of the exchange rate, as is the case with a fixed exchange-rate regime.

Under dirty float, a country maintains an independent monetary policy that allows its central bank to achieve a balance between inflation and growth. At the same time, occasional interventions in the foreign-exchange market allow the government or the central bank to avoid large swings in the exchange rates that might destabilize the economy. Countries that have a floating exchange-rate regime have to decide on the goals of their monetary policy and whether they want to engage in inflation targeting, as opposed to exchange-rate targeting, which is the case with a fixed exchange-rate regime.

Most economists consider the dirty float to be inferior to the clean float and believe that the exchange rate should be determined by the markets, while other tools of monetary policy, such as interest rates, should be used to assure the price stability.

Empirical and theoretical work suggests that when clean float is not an option, then dirty float is preferable for the developing countries, as compared to a fixed exchange-rate regime. Theoretical reasons for the superiority of a dirty float over a fixed exchange-rate regime include independence of monetary policy and freedom from currency crises. Empirical analysis also shows that countries that have more flexible exchange-rate regimes experience better economic growth on average.

International organizations such as the International Monetary Fund recommend that developing countries adopt a floating exchange-rate regime in combination with inflation targeting. As a result, the dirty float has been a dominant exchange-rate regime in the world since the beginning of the century.

Most of the countries that claim that their exchange-rate regime is floating, rather than fixed, actually engage in dirty float. For this reason, economic researchers do not simply rely on the official statement of the exchange-rate policy, or de jure classification, but rather use de facto classifications they construct based on actual volatility of the exchange rates. Most commonly used classification is constructed by Carmen Reinhart and Kenneth Rogoff in their 2004 article “The Modern History of Exchange Rate Arrangements: A Reinterpretation,” based on their study of official and black market exchange rates.

The United States has had a floating exchange-rate regime since the collapse of the Bretton-Woods system in August 1971. Until 2000, the United States has had to maintain a dirty float regime. Nevertheless, the U.S. Treasury, which is in charge of the exchange-rate policy in the United States, has not intervened in the foreign-exchange market since September 2000. Thus, since 2000, the exchange-rate policy in the United States has been a clean, or free, float.

DISABILITY

Disability, and what it means to be a disabled person, is socially, culturally, and historically created. Disability studies, and associated disability research, is a relatively recent and burgeoning arena within the social sciences. This entry shall first summarize the shift in understandings by contrasting the individual and social models of disability—a model being a set of assumptions about how an event or process operates. The entry then explores the implications of this shift in disability research and policy. Finally, the entry looks toward future possibilities in establishing the full participatory citizenship of disabled people.

DISABILITY MODELS

Within every society there are competing models of disability, with some being more dominant than others at different times. The most dominant model of disability is the individual model, which is based upon the assumption that the difficulties disabled people experience are a direct result of their individual physical, sensory, or intellectual impairments (Oliver and Sapey 2006). Thus, the blind person who falls down a hole in the pavement does so
because he or she cannot see it, and the person with a motor impairment fails to get into a building because of his or her inability to walk. Problems are thus viewed as residing within the individual. The individual model of disability is deeply ingrained and “taken as given” in the medical, psychological, and sociological literature. Even in the literature on the sociology of health and illness, disability, as disabled people define it, is basically ignored (Barnes and Mercer 1996).

The medical model can be regarded as a subcategory of the overarching individual model of disability, where disability is conceived as part of the disease process, as abnormality, and as individual tragedy—something that happens to unfortunate individuals on a more or less random basis. Treatment, in turn, is based upon the idea that the problem resides within the individual and must be overcome by the individual’s own efforts (French 2004). Disabled people have, for example, been critical of the countless hours they have spent attempting to learn to walk or talk at the expense of their education and leisure (Oliver 1996).

None of these arguments implies that considering the medical or individual needs of disabled individuals is wrong; the argument is that the individual model of disability has tended to view disability only in those terms, focusing almost exclusively on attempts to modify people’s impairments and return them or approximate them to “normal.” The effect of the physical, attitudinal, and social environment on disabled people has been ignored or regarded as relatively fixed, which has maintained the status quo and kept disabled people in their disadvantaged state within society (Oliver and Sapey 2006).

The social model of disability is often referred to as the “barriers approach,” where disability is viewed not in terms of the individual’s impairment, but in terms of environmental, structural, and attitudinal barriers that impinge upon the lives of disabled people and that have the potential to impede their inclusion and progress in many areas of life, including employment, education, and leisure, unless the barriers are minimized or removed (Oliver 1996). These barriers include inaccessible education or lack of education, inaccessible information and communication systems, inaccessible working environments, inadequate or lacking disability benefits, discriminatory health and social-care services, and inaccessible transport, housing, public buildings, and amenities (Swain et al. 2004). The social model of disability also encompasses the tragedy model in all its manifestations, such as the devaluation of disabled people through negative images in the media, including films, television, and newspapers (Darke 2004).

The social model of disability locates disability not within the individual disabled person, but within society. Thus the person who uses a wheelchair is not disabled by paralysis but by building design, lack of lifts, rigid work practices, and the attitudes and behavior of others. Similarly, the visually impaired person is not disabled by lack of sight, but by lack of reading materials in Braille, cluttered pavements, and stereotypical ideas about blindness. The social model takes a holistic approach in that specific problems experienced by disabled people are explained in terms of the totality of disabling environments and cultures (Oliver 2004).

The social model of disability has arisen from the thinking and writings of disabled people themselves, and particularly from the disabled people’s movement. The disabled people’s movement comprises organizations of disabled people in which disabled people are in positions of control.

GLOBAL ATTITUDES TOWARD DISABILITY

The experiences of disabled people in the Western world gave birth to the social model of disability. It is an expression of commonality and resistance to the dominant individual, medical, and tragedy models. To look globally, however, raises a possibly more complex and controversial picture. On one hand is the social and historical construction of disability. To be impaired and disabled in China, in Afghanistan, in Zambia, or in the United States—in the high-income “developed” or minority world and the low-income “developing” or majority world—addresses widely differing experiences and encompasses different meanings. Perhaps not surprisingly, the picture is complex, including both cultural diversity and commonalities (Flood 2005; Sheldon 2005). Provision for disabled people also varies greatly from country to country. Most countries in the majority world, for instance, do not have a welfare state.

Though attitudes toward disability are generally universally negative, there are cultural differences (Ingstad and Reynolds Whyte 1995). First are the ways in which the body and physical characteristics are given value and meaning. Western biomedical definitions of impairment are not universal, and perceptions of the body and mind vary across cultures and also change over time (Hughes 2002). Religion and the messages various religious doctrines convey about disability are also significant (Ingstad and Reynolds Whyte 1995), as is language and the notion that key concepts may not easily translate into other languages and cultures (Stone 1999b).

Notwithstanding the importance of cultural differences, subtle and not so subtle, it can be argued that commonality is an overriding picture. Commonality is engendered particularly by multideprivation, predominantly through common experiences of poverty. Disabled
people are the poorest of the poor in all countries, in terms of relative poverty in the developed world and in terms of absolute poverty in the developing world (Stone 1999a).

The establishment and growth of an international disabled people’s movement, particularly through the Disabled Peoples’ International (DPI), is in part at least an expression and realization of such commonality. As of 2007 DPI represented approximately 130 national assemblies, many of which, in turn, represent thousands of disabled individuals with all manner of impairments, including people with intellectual impairment. In 1992 DPI acknowledged that it was a human rights organization and that its membership was individually and collectively committed to global justice for disabled people. DPI is also committed to ensuring that the voice of disabled people is heard in the development of all policies and programs that directly affect them, a commitment expressed in the DPI slogan, Nothing About Us Without Us. As a result, DPI has had considerable influence in formulating the United Nations World Programme of Action Concerning Disabled Persons (1983) and the United Nations Standard Rules on Equalization of Opportunities for Persons with Disabilities (1993).

In 1992 DPI joined other international disability organizations to set up an international information network on disability and human rights with the objective of supporting disabled people’s actions at the grassroots to implement those rights. This network, Disability Awareness in Action, published a monthly newsletter, the Disability Tribune, from 1992 to 2005 and produces numerous resource kits on issues of particular concern, such as organization building, consultation and influence, campaigning, and working with the media (Hurst 2005).

DISABILITY RESEARCH AND SOCIAL POLICY
Turning to research, estimates of the number of disabled people are problematic given the variations in definitions of disability, both nationally and internationally, and the wide variety of associated impairments (Swain and French 2004). Estimates suggest that there are around 500 million disabled people in the world population. The majority, around 80 percent, of disabled people live in the developing world, the main causes of impairment being poverty, inadequate sanitation, malnutrition and a poor water supply, and more recently AIDS. Furthermore, statistics from European countries suggest that the percentage of the population that is disabled increases with age, particularly for certain disabilities such as visual impairment and hearing loss. Figures concerning comparative numbers of people in employment and education show that people with impairments are among the most disadvantaged groups around the world (Giddens 2006).

Such statistics are clearly important for disabled people, their supporters, service providers, and policymakers in establishing mandates for change. The development of the social model, however, has underpinned critiques of research, challenging who controls and produces research, priorities in funding, and ultimately the establishment of full citizenship for disabled people (Barnes 2004). Again, the central argument is that the individual model has dominated research. Negative impacts have also come from global genetic advances and assessments of disabled people’s quality of life, as well as multinational pharmaceutical companies’ hold over research, patenting, and genetic advances; the invisibility of disabled people from mainstream activity and information; and the silence of disabled people’s voices in the corridors of power and change (Hurst 2003). Statistics, whether valid or reliable, relating to the numbers of disabled people provide no information about the availability of accessible houses, transport, or so-called public buildings. Such counting of heads can carry the connotation that it is disabled individuals who create the “problem,” rather than the disabling society. The social model has fueled arguments for a different methodological approach to researching disability issues, an approach that is informed by the social model and in which the production of research is controlled by disabled people. Associated developments in social science research are generally subsumed under the umbrella term emancipatory research (Barnes 2004).

In terms of social policy, the international shift driven by the social model is evident in the establishment of rights-based policy, both civil and human. By 2007 antidiscriminatory legislation had been enacted in at least forty UN member states. There are, however, significant differences in these legislative frameworks, and general critiques focus on the lack of clear and effective enforcement mechanisms, with terms such as reasonable adjustment providing broad grounds for noncompliance—that is, antidiscriminatory legislation that allows for and legalizes discrimination against disabled people. Furthermore, the social model should not be simplistically equated with what has come to be referred to as the rights-based model. The social model encompasses and informs broader mandates for social change in realizing social justice for disabled people.

One broader front for social change has been developed under the banner of independent living (Barnes and Mercer 2006). This concept, as defined by disabled people themselves, is founded on four basic assumptions:

1. All human beings are of equal worth, regardless of the nature, complexity, or severity of their impairments.
2. Everyone, regardless of the nature, complexity, or severity of their impairments, has the capacity to

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION

Disability

make choices in controlling their lifestyles and should be supported in making such choices.

3. Disabled people have the right to exercise control over their lives.

4. Disabled people have the right to participate fully in all areas—economic, political, and cultural—of mainstream community living on an equal basis with their nondisabled peers.

The independent-living movement began through the establishment of centers for independent living (CILs), which are self-help organizations for disabled people that are run and controlled by disabled people themselves. There are now CILs or similar organizations providing support for disabled people and their families in many countries around the world. Furthermore, the idea of independent living, as conceived by disabled people, has had a notable impact on disability policy globally. Disabled people and organizations of disabled people have increasingly become involved in policymaking at local, regional, national, and international levels (Barnes and Mercer 2006).

Turning finally to the possible directions for disability policy and social science research, the goal remains essentially the same: the creation of a society in which all disabled people are able to participate as equal citizens. Under the umbrella of independent living, this includes equal access to mainstream education, paid employment, transport, “public” buildings, housing, leisure, and health-and social-care services. Mainstreaming is a key concept. The mainstreaming of disability issues within policy agendas addresses the marginalization of the needs and rights of disabled people and their treatment as “special” cases. This presents fundamental challenges to policymaking in realizing the prerogatives of flexibility, the expertise of disabled people, and the recognition that “one size does not fit all.” Mainstreaming also requires the breaking down of the physical, social, communicative, and economic barriers that prevent disabled people from exercising their rights and participating in policymaking.

The creation of participative citizenship will involve the strengthening and enforcement of legislation and procedures to ensure that disability and independent-living issues are fully integrated into policymaking at all levels: international, national, regional, and local. This includes the enactment of binding and intractable antidiscrimination legislation with effective enforcement and compliance requirements. The economic and management implications include the financing of organizations of disabled people, including CILs, and research controlled by disabled people, particularly organizations of disabled people and their representatives.

There are, furthermore, democratic and participatory possibilities afforded by the Internet and other technological developments. These technologies have opened up opportunities for dialogic, or participative rather than representative, democracy. The Internet allows a greater diversity of voices to be heard and has the potential to be profoundly democratizing. The danger is the possibility of the further marginalization of the “unconnected,” the disabled people who are the poorest of the poor, for whom survival is the political perspective and for whom sophisticated technology is not available. It is also the case that new technologies are developed within disabling societies and are not available to many disabled people unless adaptations are made that are often expensive (Goggin and Newell 2003).

Overall, paramount to the evolving direction is the emerging voices of disabled people in controlling decision-making processes across policy and research that shapes day-to-day lifestyles, opportunities, and choices. It is an ongoing struggle for a truly equitable and inclusive society with justice and full participative citizenship for all.

**DISARMAMENT**

The Oxford English Dictionary defines disarmament as the action of disarming: “the reduction of an army or navy to the customary peace footing.” Encompassing the meaning inherent in its root, disarm, “to deprive of arms, to take the arms or weapons from, to deprive of munitions of war or means of defense, to dismantle (a city, a ship, etc.),” disarmament refers to armaments and includes any measure by which their existence is reduced or eliminated.

**TYPOLOGY**

Extending far back in history, the experience of disarmament presents a varied typology. Often a unilateral obligation imposed on the loser by the winner of a conflict (e.g., on Prussia by Napoleon Bonaparte, on France in 1814 by the United Kingdom, or Germany by the Versailles Treaty in 1919), disarmament has also been a reciprocal obligation (e.g., the naval agreement between France and the United Kingdom on October 27, 1787, or the Anglo-American treaty of April 28, 1817, limiting armaments on the Great Lakes and Lake Champlain). Moreover, disarmament phenomena encompass unilateral disarmaments undertaken by states for philosophical, budgetary, strategic, or other reasons (e.g., Costa Rica, the U.S. unilateral destruction of biological stockpiles in 1969, or the Soviet Union’s unilateral reduction of forces decided on in 1988).

Disarmament in the context of a peace process following internal or international conflict has specific features. It is part of peace agreements between governments and guerrillas in Africa and Latin America (e.g., between the government of El Salvador and the Farabundo Marti National Liberation) and in the Northern Ireland peace process (Irish Republican Army disarmament ended in September 2005), leading to the disarmament of non-governmental armed groups. Finally, disarmament within the framework of peace enforcement operations (e.g., Security Council Resolution 687 of April 3, 1991, concerning Iraq) is distinct from disarmament through negotiations, even if there is some overlap in the mechanics of weapons inspection and disposal.

Compliance verification is a common challenge in all cases. The main instruments of verification are United Nations (UN) inspectors (in peace enforcement), international or bilateral commissions (in peace agreements), and verification procedures set up by international treaties. Regrettably, some disarmament treaties do not include any supervisory mechanisms.

**HISTORICAL AND LEGAL DEVELOPMENT**

Disarmament as a general goal came into focus with the Hague Peace Conferences in 1899 and 1907. The resulting rules for hostilities and the means and methods of land warfare included prohibitions against the use of certain kinds of weapons. Although a resolution adopted in 1907 agreed on the desirability of studying a reduction of military charges, the conferences failed to agree on any limitation or reduction of possession of armaments.

General aspirations for disarmament returned after World War I as part of plans for international peace and security. The Versailles Treaty limited Germany, but it was also seen as a first measure toward general disarmament. The fourth point of President Woodrow Wilson’s message...
(January 8, 1918) proposed a reduction of national armaments to limits compatible with national security and the implementation of international obligations imposed by joint action. The main organs of the League of Nations were charged with drafting plans for the general reduction of national armaments, which was to be the main instrument for the realization of peace and security. "Qualitative disarmament" was to make universal the prohibition of armaments forbidden to the vanquished powers while leaving defensive power untouched (McKnight 1983, pp. 17–20). By 1930 a draft disarmament treaty was circulated to governments for consideration, but most of the politicians at the World Disarmament Conference, which opened on February 2, 1932, believed disarmament impossible and accepted the use of force as an instrument for settling international controversies.

In the twenty-first century disarmament is linked to the principle, established in article 2 of the Charter of the United Nations, denying states the threat or the use of force. Many authors argue that the UN Charter puts less emphasis on disarmament than did the League of Nations. Under the Charter the maintenance of international peace and security is based on collective security and the right of self-defense recognized in article 51, both of which require armed forces (Kalshoven 1985, pp. 198–199). In addition, there is no general rule denying or limiting the right of states to have armed forces and hence acquire and develop armaments (International Court of Justice 1996). By contrast, the Charter charges the General Assembly to consider the general principles governing disarmament and the regulation of armaments (article 11), while the Security Council is responsible for formulating plans for the establishment of a system for the regulation of armaments (article 26).

Cold war tensions prevented any progress toward those goals, although agreement seemed near in 1954, with the Anglo-French Memorandum based on a previous U.S. document titled “Essential Principles for a Disarmament Program,” and in 1961, after the U.S.-Soviet Joint Statement of Agreed Principles—the McCloy-Zorin Principles—on general and complete disarmament. Those major failures and growing impatience with the lack of progress on disarmament gave impetus to a new concept: arms control.

In the post–cold war 1990s the world witnessed a new impetus for disarmament, with the approval of the Chemical Weapons Convention, the indefinite prohibition of the Treaty on the Nonproliferation of Nuclear Weapons (NPT), and the beginning of negotiations for new treaties (the Comprehensive Nuclear Test Ban Treaty [CTBT] or the Fissile Material Cutoff Treaty). Nevertheless, the trend of world military expenditures has been rising since 1998, accelerating to an annual average increase of around 6 percent in real terms from 2002 through 2004 (the United States accounts for 47 percent of world military expenditures and is the main representative of this trend). Additionally, no new disarmament measure has been approved and some older ones have been abandoned (e.g., the Treaty on the Limitation of Antiballistic Missile Systems [ABM]).

**CONCEPTUAL DELIMITATION**

Conceptually, the distinction between disarmament and arms control is troublesome. Some authors use the terms *disarmament* (Myrdal 1976; Kalshoven 1985; Lysén 1990) or *arms control* (Brennan 1961; Schelling and Halperin 1985) to cover all the rules and measures related to the development, production, and deployment of armaments. Nonetheless, most writers recognize a distinction, but disagree on where to draw the line on the continuum from complete reductions to measures restraining the testing, manufacture, possession, or deployment of specific types of weapon. Broad consensus assigns to the term *disarmament* the elimination or reduction of one or more categories of weapons and other measures limiting the acquisition, possession, or deployment of one or more categories of weapons. The Biological Weapons Convention, the Chemical Weapons Convention, and some of the U.S.-Soviet bilateral treaties (e.g., ABM and Strategic Arms Limitation Talks I and II) fall into the category, as does the Treaty on Conventional Armed Forces in Europe, which stands out as the major example of an international treaty reducing conventional armament. As well, the Outer Space Treaty, the Sea-Bed Treaty, the Antarctic Treaty, the Tlatelolco Treaty (for Latin America), and the Rarotonga Treaty (for the South Pacific Ocean) protect specific areas from deployment of certain weapons, while the NPT recognizes only five states as legal nuclear powers and prevents nuclear proliferation. Additionally, measures that prevent or hinder weapons development (e.g., the Partial Test Ban Treaty, the Comprehensive Test Ban Treaty, which is not in force, or the Cutoff Treaty, which is under negotiations in the Conference of Disarmament in Geneva) are more often considered a form of arms control.

**BIBLIOGRAPHY**

Placement of the term management next to this category of extreme events implies a belief that some measure of control, maybe prevention, is possible. This is a relatively new idea that remains poorly understood and highly controversial. Understanding this concept requires exploration of four subtopics: (1) types of disasters, (2) social vulnerability trends, (3) social system consequences, and (4) planning and management policy.

TYPES OF DISASTERS

In August 2005 many throughout the world watched on television as thousands of American citizens suffered for days following the destruction caused by Hurricane Katrina. Despite evacuation orders from local and state officials, more than 1,300 people perished. Most deaths resulted from flooding in the New Orleans area after portions of the levee system failed. Not since the terrorist attacks of September 11, 2001, had the world witnessed such disaster-caused suffering within the United States. Elsewhere, of course, the scope of disasters has been far worse. Examples include the earthquakes in Indonesia on May 27, 2006, that killed over five thousand people and the massive tsunami on December 26, 2004, that struck coastal areas along the Indian Ocean in such far-apart places as Thailand, Sri Lanka, and India. The 2004 tsunami alone killed at least 280,000 people. These contrasts hint at the many types of disasters, commonly divided into three categories: (1) natural, (2) technological, and (3) conflict-related.

Natural Disasters Natural disasters include both a wide range of extreme weather-related events and those resulting from geophysical forces, such as earthquakes (Mileti 1999). Extreme weather events include hurricanes like Katrina, which are known as “typhoons in the western North Pacific and cyclonic storms or tropical cyclones in other areas” (World Meteorological Organization 2005, p. 1). The most deadly hurricane to hit the United States struck Galveston, Texas, on September 8, 1900. Estimates of the death toll from this hurricane vary, but at least six thousand people died. In 1992 Hurricane Andrew caused property damage in Florida and Louisiana that totaled about $30 billion. Andrew held the record until Katrina, which had loss estimates as high as $200 billion (Select Bipartisan Committee 2006).

Tornadoes, another type of extreme weather event, occur throughout the United States, especially in the Midwest. The Great Tri-State Tornado of 1925 left 695 people dead in Missouri, Illinois, and Indiana; it was the largest tornado-related death toll as of 2006. Although less deadly, flood disasters cause more property damage than any other type of weather-related event (Mileti 1999, pp. 72–82). The deadliest flood within the United States
Disaster Management

occurred in Johnstown, Pennsylvania, in 1889 when over two thousand people died. Other weather-related disasters result from drought, extreme heat or cold, fog, hail, blizzards, avalanches, lightning, and wildfires.

Geophysical disasters, such as earthquakes and volcanoes, have also occurred in the United States. For example, the 1906 earthquake in San Francisco left 503 people dead. While only 61 people died in the Northridge quake that shook the Los Angeles area in 1994, a new record in earthquake-related property loss was reached: $30 billion. These losses pale, however, when compared to earthquake-related losses experienced worldwide in such places as China in 1927 (200,000 killed); Armenia in 1998 (25,000 killed); and India in 2001 (20,000 killed).

In 1868 Hilo, Hawaii, was devastated by massive ocean waves originating from earthquakes in Peru and Chile. Similarly, the 1964 Anchorage earthquake produced tsunamis that struck Valdez, Alaska, and Crescent City, California. Records of volcano-related deaths have been kept since the time of the eruption of Mount Vesuvius in Italy in 79 CE, when approximately twenty thousand people died in Pompeii. In 1902, for example, on the island of Martinique in the Caribbean, approximately forty thousand people died when the city of Saint Pierre was destroyed after Mount Pelée erupted. Less deadly volcano disasters have occurred with regularity, including the 1980 eruption of Mount Saint Helens in Washington state, which killed sixty people.

Finally, epidemics of disease constitute a major risk. Although mass immunization programs have curtailed diseases such as diphtheria from which many died before the early twentieth century, a future pandemic could kill thousands, maybe millions. The 1918 influenza outbreak probably started in Haskell County, Kansas, and rapidly spread worldwide, in part because of troop movements during World War I (1914–1918). Approximately 100,000,000 people died from the flu during this pandemic, far more even than died from the infamous Black Death plague of the Middle Ages (Barry 2005).

Technological Disasters Technological disasters reflect a wide range of events stemming from transportation, building, and energy-production failures. For example, airplane and ship failures are illustrated by such disasters as the 1999 Egypt Air crash near Nantucket Island, Massachusetts (217 killed), and the sinking of the Titanic in 1912 (1,503 killed). Structural fires, like that which broke out in the Iroquois Theater in Chicago in 1903 (602 dead), and building collapses are another dimension of this category. Energy-production disasters include such events as the explosion and fire that occurred in Texas City, Texas, in 1947, which killed 516 people and injured more than three thousand. Such events pale, however, next to the thousands killed when a gas leak caused a massive explosion at the Union Carbide plant in Bhopal, India, in 1984, or the Chernobyl nuclear plant disaster in Ukraine in 1986. Experts have estimated that the Chernobyl disaster caused some ten thousand cancer cases within nearby communities and approximately five thousand deaths (Segerståhl 1991).

Conflict Disasters Conflict disasters include wars both among and within nations. The American Civil War (1861–1865), for example, resulted in the deaths of over 500,000 troops. American military casualties during World War II (1939–1945) are estimated at just over 400,000. And these numbers do not include civilian losses, or in the case of World War II, losses of both types from other countries.

Increasingly, however, violence by nonstate militants has become a concern. Using violence toward noncombatants as a political strategy, terrorists have precipitated increased efforts at civil protection. The use of commercial airliners as weapons on September 11, 2001, resulted in over three thousand deaths at the World Trade Center in New York, the Pentagon near Washington, D.C., and a field near Shanksville, Pennsylvania. Increased attacks on “soft targets” such as subways, as occurred in London in July 2005, and hotels, as in Amman, Jordan, in November 2005, illustrate another form of increased vulnerability. Should weapons of mass destruction, such as nuclear bombs, become available to terrorist groups, the destructive potential increases greatly. Finally, civil disorder may erupt within a society when heightened feelings of deprivation and disenfranchisement are ignited by critical incidents, as occurred in Paris and London in 2006 when students and young workers protested new laws regulating employment termination.

SOCIAL VULNERABILITY TRENDS

Human populations are becoming more vulnerable to disasters, especially those of catastrophic scope, for many reasons. In past centuries, people believed disasters were caused by forces outside of human control. Floods, volcanoes, and other natural disasters were labeled “acts of God” and were interpreted as punishment or disfavor. Russell Dynes (2000) has proposed that a naturalistic or “modern” interpretation of disaster events first occurred in 1755 following a major earthquake in Lisbon, Portugal. This earthquake killed at least ten thousand people, although some estimates place the toll as high as seventy thousand. Civil authorities led efforts to rebuild the city and gradually increased their authority over the church in political matters. This shift led to alternative thinking about attribution for disasters. Although not universally accepted even today, “naturalistic” interpretations reflect-
ing Enlightenment philosophy paved the way for new approaches to disaster management. Unfortunately, numerous trends are acting in concert to place more and more humans at risk despite accelerated efforts at management. Among these are population changes, increased reliance on technology, and climate change.

As the world population increases, there are more potential disaster victims. Beyond larger numbers, however, more people are moving into areas of high risk. For example, the coasts of Florida and Texas have witnessed explosive growth since the mid-1970s. In addition, increases in the numbers of elderly and poor, of homes led by single mothers, and of people living in mobile homes add a further dimension to America’s social vulnerability. Mobile homes, for example, provide affordable housing to millions, but offer minimal protection during violent storms, especially tornadoes. Not only are more people living in areas that are wind, flood, or avalanche prone, the structures within which many dwell offer inadequate protection. In poorer countries, the use of stone and tile building materials that collapse during earthquakes is a parallel problem.

Climate change, which has been documented in numerous ways, will be reflected in future disasters. For example, increased heat retention by miles of pavement and high-rise structures is related to new storm patterns, and residential and commercial construction is expanding into geographic areas already known to be flood or tornado prone. Moreover, while annual rainfall has remained stable, there is an increased frequency of intense downpours, which cause localized flooding and traffic accidents. Forecasts for a rising sea level and warmer ocean temperatures imply similar pattern change for hurricanes.

These vulnerability trends are exacerbated by shifts in social, economic, and political patterns, such as the globalization of the economy and an increase in feelings of deprivation that reflect long-standing patterns of inequality and social injustice. There is no single trend that contributes to increased vulnerability; rather, it is the cumulative effects of a series of both social and physical forces that result in higher risk levels. These risks are not distributed uniformly, but are skewed, with the poor, elderly, and ethnic minorities at higher risk.

SOCIAL SYSTEM CONSEQUENCES
Disasters have important consequences for social systems. Smaller systems, such as families, may experience short-term oscillations. For example, divorce rates and marriage rates generally drop in the first few months following a disaster (Cohn and Cole 2002). However, after a six-month spike downward and then upward, trend lines smooth out; that is, some put off marriage for a few months, and then join others who were planning to marry at a later date—hence, a drop, then an increase, followed by a continuation of the prior trend line. Some studies have documented that there is a longer delay in the divorce pattern. Disasters appear to cause some to remain married, at least temporarily, and to drop their plans for divorce. Within these macrosystems, however, some changes are permanent. For example, studies have documented that many disaster victims, especially those helped by kin during recovery, report closer kin ties years later.

After a disaster, relatives may interact more frequently, and people maintain closer links to both kin and friendship groups, although participation in voluntary associations decreases somewhat. The sole exception is religious organizations, which show slight increases. Hence, after disasters, microsystems reflect tighter links to kin, friends, and religious organizations (Drabek 1986).

Macrosystems, such as communities and societies, experience disaster consequences of at least four types. First, there is an acceleration of preexisting trends. Following the 1964 Anchorage earthquake, for example, William Anderson (1970) documented that numerous changes planned within organizations prior to the earthquake were implemented more rapidly. In another case, social stratification was widening in the Miami area prior to Hurricane Andrew. After the hurricane, Walter Peacock and colleagues (1997) documented acceleration of this trend.

A second consequence of disasters for macrosystems is that disaster preparedness and prevention efforts are increased. Newer, enhanced warning systems may be implemented, as are flood protection measures, for example. Unfortunately, as noted above, these actions rarely take into account the forces that are placing more people at risk, so the net gain may be minimal.

Third, various scholars, including Pitirim Sorokin (1889–1968) and Karl Marx (1818–1883), have proposed that some disasters deflect social, economic, and political developments. For example, the conflicts that developed between business interests, government programs, and upper-class elites during the reconstruction following the 1972 earthquake in Managua, Nicaragua, may have led to the collapse of the Somoza regime in 1979. Other scholars, including Jared Diamond (2005), reject such single-factor explanations and include disasters within a multifactor framework that more convincingly accounts for such changes as total societal collapse. Such collapses occurred on Easter Island around the mid-1800s and among the Anasazi in southwestern Colorado and northern New Mexico about 1300 (Diamond 2005, pp. 112, 154).

The fourth consequence of disasters for macrosystems is policy change. Consistent with Anderson’s findings, however, these often reflect policy initiatives that were in process prior to the event. For example, T. Joseph Scanlon and John Handmer (2001) documented the
impact on gun-law reform in Australia of a 1996 massacre in Port Arthur in which a lone gunman killed thirty-five people. Reform proposals had been advanced in Australia earlier, but had never been adopted. One year after the massacre, however, reform legislation was implemented. Similarly, in the United States in the years before 2001, several commissions had recommended the establishment of a department of homeland security and other terrorist prevention policy changes. Following the attacks of September 11, 2001, some of these proposals were adopted. Despite serious failures in the official response to the attacks, including a lack of multiagency communication, additional reform proposals remained controversial years later (National Commission on Terrorist Attacks 2004).

PLANNING AND MANAGEMENT POLICY
Following numerous large-scale disasters during the 1960s, state and local governments exerted pressure on the U.S. Congress for reorganization. As various types of disaster events occurred, different federal agencies created event-specific programs for recovery and mitigation in response to floods, earthquakes, hurricanes, and other disasters. These programs evolved over time and paralleled the coterminous development of programs designed to protect civilian populations in the event of an enemy attack. In 1979 President Jimmy Carter established the Federal Emergency Management Agency (FEMA). This agency was to provide a single point of federal contact for state and local governments and other entities, including nongovernmental agencies like the American Red Cross. FEMA also was to be the lead agency within the federal bureaucracy for coordination of all disaster activities, regardless of the type. This all-hazard agency was to be operative across the entire life cycle of all disaster events, with responsibility for coordinating mitigation and preventive actions (e.g., flood-zone mapping), preparedness, response, and recovery. The first line of response remained with local and state governments, but when events created demands that overran their resources, they could request FEMA assistance. A regularized process, as opposed to the ad hoc arrangements of the past, was established through a presidential declaration when conditions warranted (Drabek and Hoetmer 1991).

During the response to Hurricane Andrew in 1992, President George H. W. Bush was severely criticized for FEMA’s slow and inadequate response. His successor, President Bill Clinton, placed a priority on strengthening FEMA, and eventually elevated the agency directorship to cabinet-level status. Recruitment and training promoted professionalism within FEMA and within state and local emergency management agencies. FEMA staff facilitated these enhanced state and local capabilities by emphasizing researched-based principles, including the view that disaster planning is a process, not a product, and that disaster plans must be prepared by representatives from the agencies that will implement them. In addition, colleges across the United States established new degree programs in emergency management (Drabek 2004).

Following the 9/11 attacks, FEMA was transferred into the newly created Department of Homeland Security. Despite continuity in name, many FEMA programs experienced reduced funding as terrorist-related program priorities were implemented. During and following the response to Hurricane Katrina, FEMA was criticized severely. While various congressional investigations pointed out failures within state and local government agencies, FEMA was hit hardest, especially in the public perception, and numerous difficult policy issues were raised by the post-Katrina reviews. Among these was whether or not FEMA should be abolished and its functions reassigned within various units of the Department of Homeland Security. Others proposed that FEMA should be upgraded and made into a stand-alone agency independent of the Department of Homeland Security. Many who testified before congressional committees voiced concerns about intergovernmental partnerships, specifically the degree of autonomy and flexibility of state and local emergency management agencies. The degree to which the emergency management function should be conceptualized within a common standardized system became the operative policy question. Many expressed concern that terrorism preparedness had been pushed into high priority, while focus diminished on other types of disasters. Finally, the role of the military in disaster response was revisited.

Consideration of all of these policy matters will be deflected by future disaster events, whatever they may be. When they occur, policymakers will be pressed to demonstrate why they did not do more to prepare. Thus, disaster policy will continue to evolve and reflect both specific events and public perception of the threats believed to be the most harmful.

Discounted present value is a concept in economics and finance that refers to a method of measuring the value of payments or utility that will be received in the future. Most people would agree that receiving $1,000 today is better than receiving $1,000 in a year, because $1,000 today can be used for consumption or investment. This feature is referred to as time value of money—a given amount of money today is better than the same amount of money in the future. Discounted present value allows one to calculate exactly how much better, most commonly using the interest rate as an input in a discount factor, the amount by which future payments are reduced in order to be comparable to current payments.

There are two ways to think about discounted present value—transferring money from the future to the present via borrowing or transferring money from the present to the future via lending. In both cases the interest rate at which one can borrow or lend is a crucial part of the formula.

Suppose a firm is scheduled to receive a payment of $1,000 in a year. To understand how much this payment is worth to the firm today, we can calculate how much the firm can borrow today against that payment:

\[ x \times (1 + i) = 1000, \]

where \( i \) is the interest rate. Then, \( x = 1000/(1 + i) \). The factor \( 1/(1 + i) \) by which we multiply the future payment is called a discount factor.

If the payment is scheduled to arrive in two years instead, we can use a two-step approach. Assuming the interest rate is the same for two years, a year from today the value of the payment will be \( 1000/(1 + i) \), which today is worth

\[ (1000/(1 + i)) \times 1/(1 + i) = 1000/(1 + i)^2. \]

Thus, for discounting the payments far in the future the compound interest rate is used.

To calculate the discounted present value (DPV) of a stream of future payments, one has to discount each payment appropriately and then add them up. If we denote the payment in each future year by \( y_i \), where \( i \) is the year, then:

\[
\text{DPV} = y_1/(1 + i) + y_2/(1 + i)^2 + y_3/(1 + i)^3 + \ldots + y_T/(1 + i)^T = \sum_{i=1}^{T} y_i/(1 + i)^i
\]

The formula above makes a set of assumptions that are important for the result: (1) interest accrues and is compounded annually; (2) the interest rate is constant over time; and (3) the payments occur for \( T \) years, starting one year from today. Altering each of these assumptions would lead to different results. To properly calculate the dis-
counted present value of future payments, one also has to
use the most appropriate interest rate in calculations.

In addition, individuals might be simply impatient
and prefer to receive their utility today instead of waiting
for the future payment, even if interest will accrue. This
impatience is measured with the individual discount fac-
tor, which can be multiplied by the market discount fac-
tor described above to measure the discounted present
value of future utility in terms of today's utility.

The concept of discounted present value is com-
monly used in all areas of finance, including decisions
individuals commonly make—taking a mortgage credit
for purchase of a house, financing the purchase of the car,
and the like. Every firm uses the discounted present value
of their future cash flow to assess the value of their proj-
ects. Investors use discounted present value to estimate the
return on their investment. Lawyers use discounted pres-
ent value in lawsuits to calculate the value of settlement in
cases when damage to a client’s health deprives him or her
of future income.

DISCOURAGED UNEMPLOYMENT
SEE Discouraged Workers.

DISCOURAGED WORKERS
Discouraged workers are persons who, discouraged about
their prospects of finding work, have given up their job
searches and are therefore no longer officially counted as
unemployed.

The Bureau of Labor Statistics (BLS) of the U.S.
Department of Labor defines discouraged workers as
those who report that they want a job but did not look for
work in the past four weeks because they believe that no
work is available in their line of work or area; they have
previously not been able to find work; or they lack the
necessary education, skills, or experience, or employers
consider them too young or too old, and so on.

In 1994 the BLS added two further criteria to the
definition. To be counted as a discouraged worker, persons
must have looked for a job within the past year (or since
their last job, if they worked during the year) and must
indicate that they were available to start work during the
prior week if a job had been offered. These changes were
an outgrowth of suggestions made in the 1979 report
of the National Commission on Employment and
Unemployment Statistics (the Levitan Commission),
which criticized the definition then in use as too subjec-
tive and too arbitrary. The commission recommended a
measure based on clear evidence of prior job search and of
availability for work. The tightened definition cut the
number of discouraged workers from a range of 1.1 to 1.2
million throughout 1993 to 541,000 in the first quarter
of 1994 (the latter figure is available only on a not-season-
ally-adjusted basis).

Discouraged workers are excluded from the ranks of
the unemployed because the BLS counts as unemployed
only those jobless workers who have actively looked for
work within the past four weeks or who have been laid off
from a job to which they expect to be recalled. Recognizing,
however, that an argument can be made for counting dis-
couraged workers as unemployed, the BLS publishes as an
alternative to the official unemployment rate each month a
rate that includes discouraged workers. Thus, when the
BLS reported that that the official unemployment rate was
4.8 percent in July 2006, it also noted that adding the
428,000 discouraged workers to both the unemployed and
the labor force raised the rate to 5.0 percent.

The number of discouraged workers rises when the
economy weakens and falls when the economy improves.
For example, the number rose from 1,109,000 to
1,793,000 during the recession that lasted from the third
quarter of 1981 to the fourth quarter of 1982, and it then
dropped to 813,000 by the next economic peak, in the
third quarter of 1990. As a result, the changes that occur
in the official unemployment rate, which excludes dis-
couraged workers, understate the worsening of the labor
market that occurs in bad times and the improvement that
occurs in good times.

The definition of discouraged workers differs among
countries. In Canada, for example, discouraged workers
must have looked for work within the past six months,
rather than within the past year. A BLS study warns that
international comparisons of the number of discouraged
workers "should be viewed with caution because the

DISCOURSE
A sentence is a systematic arrangement of words. A discourse is a systematic arrangement of sentences. The domain of discourse includes various genres—such as narrative, epic, journalistic, or poetic—and thematic fields, from the actuarial to the zoological. It includes register—high and low, technical and vernacular, polite, allegorical and literal, and so on—and modes, from the written to the spoken, and from monological to conversational. It also includes the dimension of style, as well as diverse functional orders, including referential, heuristic, imperative, and connotative.

So encompassing a category might seem to be of dubious analytical rigor. But perhaps precisely because it is such a hodgepodge, discourse confronts the analyst with the formal dimensions of language, but also with the diverse conditions of its production and use. It serves as a sociocultural tool kit, whose astonishing multiplicity of instruments can be deployed to characterize the world, from one context to another, and to realize a great variety of other ends. An analytical engagement with discourse has come to define sociolinguistics (see Goffman 1981; Romaine 2000; Trudgill 1974), the ethnography of communication (Gumperz and Hymes 1986; Saville-Troike 1982) and more specialized pursuits such as ethnopoetics (Sammons and Sherzer 2000) and metapragmatics (Lucy 1993). The chief philosophical predecessors of this engagement were Ludwig Wittgenstein’s treatment of “language games” in his Philosophical Investigations (1953) and John Austin’s treatment of speech acts, or “performatives,” such as promising or pronouncing a couple to be wed in How to Do Things with Words (1962).

Since the later 1960s, however, the analysis of discourse has ceased to be the province of linguists and linguistic anthropologists alone. It has instead emerged as one of the leading preoccupations of social thought, and of cultural studies more broadly (see Howarth 2000; Mills 2004). That it has done so is closely related to the increasing contemporary saliency of two other topics that are often regarded as hallmarks of the post-structuralist turn in social and cultural critique. One of these centers on the variable historicity of the many collective systems in which human beings take part, or of which they are a part (Attridge, Bennington, and Young 1987). The other centers on the ways in which, and the extent to which, such systems are implicated in the reproduction of economic and political domination. Well before the post-structuralist turn, however, the Marxist political theorist Antonio Gramsci (1891–1937) set an influential, if partial, precedent in conceiving of the trajectory of the dynamics of language, history, and power as unfolding in the contest between the prevailing or “hegemonic” ideologies of a ruling class and the counterhegemonic ideologies of the class destined to succeed them. Several decades later, the structuralist Marxist Louis Althusser (1918–1990) supplemented Gramsci’s schema with the still-current postulate that bourgeois ideology is, at base, a discursive apparatus through which persons of authority “interpellate” and, in so doing, subject other persons to authority (Althusser 1971, p. 170–178).

At once post-structuralist and post-Marxist, Michel Foucault’s (1926–1984) oeuvre is the source of the conception of discourse most widespread today. For Foucault, discourse is always contestable, always “tactically polyvalent,” though by no means is it always the tactical weapon of one or another economically defined class. Discourse bears authority by definition. Its domain is not equivalent to that of opinion in general. Nor does its authority necessarily rest on the hegemony of the material interests that it may serve. The proper measure of discursive authority is, for Foucault, the always somewhat conventional measure of what constitutes knowledge. Knowledge is not, per se, a kind of power. Discourse approached without reference to the material practices it serves and informs can yield no more than a purely speculative analysis of domination. Just so, Foucault’s research into the establishment of the mental asylum, the prison, and sexology reveals that those discourses of life, labor, and language that, since the early nineteenth century, have been recognized as “human sciences” have provided the rationale for the imposition of entirely material apparatuses of anthropological classification, compartmentalization, and confinement. Yet Foucault’s diagnosis of such discourses of “subjectivation” affords no hope of radical liberation (Foucault 1998, pp. 459–460). As Althusser seems also to have believed, human beings have nothing else to be but discursively articulated and discursively “interpellated” subjects. They might still strive to render the terms of their subjectivation more accommodating and less absolute.
**DISCRIMINANT VALIDITY**

**SEE Validity, Statistical.**

**DISCRIMINATION**

The online version of the *American Heritage Dictionary of the English Language* (2000) defines *discrimination* as, “Treatment or consideration based on class or category rather than individual merit; partiality or prejudice.” Discrimination is a broad and multidimensional concept that covers all acts of preferring one thing, person, or situation over another (Block and Walker 1982, p. 6). In this broad sense, discriminatory behavior can occur within many economic or social activities of daily life. For example, the preference of a high school basketball coach for a taller player over a shorter one in selecting a team or an employer paying an African American worker less than a white worker for the same work would both fall under the heading of discrimination. While the latter act carries an unambiguously negative connotation, few people would consider the former act to be malevolent. Thus, discriminatory behavior does not always imply injustice or prejudice. While understanding this distinction is important, a more relevant discussion of discrimination should emphasize the types of discriminatory acts that are socially and economically unjust, the type of acts that have caused the word *discrimination* to gain an unambiguously negative meaning. Denying or restricting equal opportunity in housing, education, and employment to members of a certain demographic group, such as African Americans, women, or other minority groups, constitutes an act of discrimination that violates common notions of social and economic justice and points to a need for policy intervention.

**LABOR-MARKET DISCRIMINATION**

One of the most common forms of discrimination, *labor-market discrimination* refers to differential treatment of workers within the labor market. It occurs when individual workers with identical productivity characteristics are treated differently with respect to hiring, occupational access, promotion, wage rate, or working conditions because of the demographic groups to which they belong.

**Taste for Discrimination** Gary Becker, the 1992 Nobel Prize recipient in economics, laid the groundwork for the mainstream economic approach to the analysis of discrimination in *The Economics of Discrimination* (1957). Becker’s theory of discrimination represents an example of the neoclassical economics approach. He introduces the
concept of _taste for discrimination_ to translate the notion of discrimination into the language of economics. According to Becker:

If an individual has a "taste for discrimination," he must act as if he were willing to pay something, either directly or in the form of reduced income, to be associated with some persons instead of others. When actual discrimination occurs, he must, in fact, either pay or forfeit income for this privilege. This simple way of looking at the matter gets to the essence of prejudice and discrimination. (Becker 1957, p. 14)

**Employer Discrimination** In cases of employer discrimination, employers with a taste for discrimination act as if employing, for example, African American workers imposes psychological costs that they are willing to pay. The measure of their willingness to pay can be translated into monetary terms by the _discrimination coefficient_. To illustrate, suppose that the costs to an employer of employing an African American worker and a white worker are \( W_{aa} \) and \( W_{aw} \), respectively. If the employer possesses a taste for discrimination against the African American worker, he will act as if the actual cost were \( W_{aa} (1 + d) \), where \( d \), a positive number, is the discrimination coefficient. The prejudiced employer will be indifferent when choosing between a white worker and an African American worker when the cost of hiring each worker is, to him, equal—that is, \( W_{aw} = W_{aa} (1 + d) \). A clear implication is that the African American worker will be hired by the discriminating employer only if his wage rate is below that of a white worker. More precisely, the African American worker will only be hired if his wage rate is less than that of a white worker by at least the amount of the discrimination coefficient.

**Employee Discrimination** The source of discrimination may also be the prejudice of fellow employees. For instance, white workers may possess discriminatory preferences against African American workers and avoid situations where they have to work alongside them. The extent of employee prejudice can be monetized by the discrimination coefficient, using an analogy parallel to employer discrimination. A white worker who is offered a wage \( W_w \) for a job will act as if this wage rate is only \( W_{ww} (1 - d) \), where \( d \) is the white worker's discrimination coefficient. The white worker will agree to work with African Americans only if he or she is paid a premium equal to \( W_w d \).

**Customer Discrimination** Another source of discrimination in the labor market results from the prejudice of customers. For example, white customers may prefer to be served by white workers, which would reduce the demand for goods and services sold or served by African American workers. More formally, suppose the actual price of a good or a service is \( p \). Then a white customer would act as if the price of this good or service were \( p(1 + d) \) when faced with an African American worker. One of the implications of customer discrimination is that it would result in a segregated workforce within a firm, with white workers being placed in positions with high customer contact and African Americans working in positions with minimal customer interaction.

**Predictions of Becker’s Theory** One of the predictions of Becker's theory is that the labor market will become completely segregated over time. This prediction can be illustrated using employee discrimination. In the presence of employer discrimination, nondiscriminating and profit-maximizing employers would never choose to hire both white and African American workers because employers want to avoid paying a premium to white workers. Instead, they would hire only African American workers who offer the same productivity as whites at a lower wage.

Another prediction of Becker’s theory is that discrimination cannot persist in the long run in a competitive market where firms can enter and exit freely. This is because free entry by nondiscriminating employers will force discriminating employers out of the market. For example, nondiscriminating employers will hire equally productive African American workers at a wage that is lower than that offered to white workers. Nondiscriminating firms thus have a cost advantage over discriminating firms, and the forces of competition would drive the discriminating firms out of business. As more nondiscriminating firms enter the market, the demand for minority workers will rise, which will gradually erode the wage differentials between different groups of workers. Therefore, Becker’s theory suggests that policies aimed at lessening or eliminating barriers to competition in the market place should help reduce discrimination and wage differentials.

Economists have widely tested the predictions made by Becker’s model. For example, Orley Ashenfelter and Timothy Hannan (1986), using data from the banking sector, showed that the share of women employed in a firm is negatively related to the extent of competition in a geographical area. Another study by Judith Hellerstein, David Neumark, and Kenneth Troske (2002) found that, among plants with high levels of market power, those that employ more women are more profitable than those employing fewer women; no such relationship was found for plants with low levels of market power. These findings are consistent with Becker's prediction that discrimination can exist in situations where firms possess market power.
Although Becker's analysis of discrimination has found wide support among economists, criticism has been raised about the predictions of the theory. For example, it has been pointed out that, despite the model's predictions, competitive market forces have not eliminated discrimination, and wage disparities between different demographic groups have not completely disappeared (Darity and Mason 1998). Others have shown that the prediction of a segregated market does not accord with today's real world; furthermore, more segregated workforces tend to generate more wage inequality, not less (Mason 1999). There is also evidence of skin-tone differences in wages among underrepresented minorities (Mason 2004). Finally, several studies find that market competition does not decrease the degree of discrimination practiced within a sector, as predicted by Becker (Coleman 2004; Agesa and Hamilton 2004). Alternative theories of discrimination have been proposed to provide explanations for these issues.

**Statistical Discrimination** Discriminatory behavior can also occur because employers have limited information about the productivity characteristics of potential employees. Therefore, employers' hiring decisions may rely on average group characteristics based on factors such as race and gender. As a result, individuals with identical productivity characteristics will have different labor-market outcomes because of the average quality of the group to which they belong. Judging individuals on the basis of their average group characteristics is referred to as statistical discrimination.

For example, suppose an employer has to choose between a male and female job applicant. Assume further that the observable personal characteristics of these two applicants, such as age, years of education, previous work experience, test scores, and recommendation letters, are identical and that both of them performed equally well at the job interview. An employer, having to make a hiring decision between the two applicants, may decide to offer the job to the male applicant based on the employer's belief that female workers are more likely to quit their jobs than their male counterparts because women are likely to engage in childrearing. The employer makes a decision using statistics about the average group characteristics of the applicants. It is important to note that the statistical information used by the employer may or may not be accurate. In this example, whether or not women actually have higher quit rates than men is not relevant to the hiring outcome. While the behavior of some employers engaging in statistical discrimination could be rooted in prejudice, it is also possible that these actions are based purely on nonmalicious grounds. Statistical discrimination can result from decisions that may be correct, profitable, and rational on average.

Statistical discrimination helps explain how racial and gender differences between workers of equal productivity can exist in the labor market. It also explains how discrimination can persist over time. Unlike Becker's taste-for-discrimination model, the employer does not suffer monetarily from practicing statistical discrimination. On the contrary, the discriminating employer can benefit from this behavior by minimizing hiring costs. Therefore, there is no compelling reason for discrimination, and wage differentials between males and females or African Americans and whites tend to disappear in the long run in the presence of statistical discrimination.

While much of the focus on statistical discrimination concerns the labor market, such practices can be observed in different sectors of society as well. One nonmarket example of statistical discrimination is the observed racial differentials in policing patterns. John Knowles, Nicola Persico, and Petra Todd (2001) found that police search vehicles driven by African American motorists for illegal drugs and other contraband far more frequently than those of white motorists. If the motive behind this police behavior is the belief that African Americans are more likely to commit the types of traffic violations that police use as pretexts for vehicle searches, this type of behavior is an example of statistical discrimination.

However, William Darity and Patrick Mason (1998, p. 83) argue that statistical discrimination cannot be a plausible explanation for long-lasting discrimination. They assert that employers should realize that their beliefs are incorrect if average group differences are perceived but not real. If, on the other hand, these differences are real, then employers should develop methods to measure future performance accurately rather than engaging in discriminatory behavior, especially in a world with strict antidiscrimination laws.

**NONCOMPETITIVE MODELS OF LABOR-MARKET DISCRIMINATION**

The models of discrimination discussed above assume that firms operate in competitive markets. However, discriminatory motives can also be drawn from circumstances in which employers possess some degree of market power in wage determination. Alternative explanations of discrimination have been offered for these circumstances.

One of these alternative explanations is occupational crowding. The occupational crowding model of discrimination, advanced by Barbara Bergmann (1971), hypothesizes that labor-market disparities between African American workers and white workers (or males and females) are not due to a “taste for discrimination” by employers, but rather to a deliberate policy of segregating African American workers (or females) into lower-paid occupations. Crowding these groups into low-paying
occupations and limiting their access to other occupations reduces their marginal productivity in comparison with that of white (or male) workers. At the same time, the exclusion of minorities from high-paying jobs pushes up the wages of whites, including those who might earn lower wages in the absence of discrimination.

However, profit-maximizing motives should induce some firms to start replacing higher-paid white (or male) workers with equally productive but cheaper African American (or female) workers. This process would eventually eliminate wage disparities between the two groups. In this case, the observed wage disparities can be explained by the presence of noncompetitive forces, such as barriers to worker mobility between occupations.

An alternative explanation of discrimination in the context of a noncompetitive market was developed by the British economist Joan Robinson (1933). Robinson argued that in a monopsonistic market (a labor market with a single employer), profits can be increased by discriminating against some workers if the labor supply elasticity (responsiveness to wages) of African American (or female) workers is less than that of white (or male) workers. Although this model offers a plausible explanation for monopsonistic markets, its applicability is limited because these types of markets are relatively rare.

Another explanation for discrimination was put forth by radical economist Michael Reich (1981). Reich criticized the neoclassical approach to discrimination on several grounds and offered an alternative explanation based on class conflict. According to Reich, a firm’s output and profitability depend not only on the amount of labor hired, but also on the level of collective action or bargaining power among workers within the firm. He further argued that bargaining power is a function of the wage and employment disparities between African Americans and other workers in the firm. Therefore, discriminatory practices, such as paying equally productive African American workers less than white workers or denying employment to African Americans, generates animosity in the work force, which reduces the bargaining power of workers. As a result of the workers’ weakened bargaining power, employers are able earn more profits. Unlike Becker’s model, a competitive employer is a direct beneficiary of discrimination in Reich’s model.

Another economist, William Darity (1989), criticized Reich’s emphasis on the employer in the creation of class conflict and argued that racism among the white working class was not necessarily due to collusive behavior by capitalists, but rather to collective racist action by white workers. According to Darity, in a hierarchical society where occupations are stratified so that some occupations are preferred over others, discrimination occurs as members of different ethnic cultures fight over preferred occupations. One prediction of this explanation is that discrimination cannot be eliminated through government interventions like affirmative action that redistribute occupational positions; it can only be rooted out by eliminating the social hierarchy, because it is the main source of ethnic conflict that results in discrimination.

Patrick Mason (1999) showed that if workers face differential conditions of labor supply, if employers are able to limit the power of labor coalitions, and if racial identity is an important factor in job competition among workers, then competitive profit-maximizing firms may persistently discriminate in their labor-market decisions.

MEASURING LABOR-MARKET DISCRIMINATION

Although it is relatively easy to detect discrimination, it is much more difficult to measure it. The difficulty arises from the fact that not all the disparity between, say, the wages of African Americans and whites is due to labor-market discrimination. These two groups may also differ in their productive characteristics because of pre-labor market discrimination (for example, African Americans receiving less and lower-quality education due to educational discrimination). Then, the disparity must be due in part to differences in the productivity characteristics between the groups. It is important to account for all of these productivity characteristics in order to obtain an unbiased estimate of the true measure of discrimination. After accounting for productivity characteristics, the residual in disparity would then represent a measure of discrimination.

CONCLUSION

Discrimination, whether it occurs in the form of denying employment, housing, or education to members of a particular group, places countless burdens on its victims and on society as a whole. These burdens are both economical and social. By provoking hostility between different groups, discrimination may undermine social harmony, leading to such undesirable social consequences as increased rates of crime. Discrimination also has adverse economic consequences because the earnings of those who face discrimination will be depressed and their career paths will suffer. As a result, the rate of poverty will increase among these groups. The negative consequences of poverty on education, health, crime, and the overall economy will further increase the costs of discrimination for society. Furthermore, many of these negative effects are likely to persist over generations. Thus, discrimination will not only place a cost on its current victims, it will also punish future generations, even if these future generations live in a society without discrimination.
Although the discussion above focuses on discrimination based on race or gender, discriminatory behaviors can and do target all minority groups, including the elderly, teenagers, the disabled, homosexuals, ethnic groups such as Hispanics, and members of certain religions such as Jews and Muslims.

Price discrimination is a widely used marketing tactic. It is present when two or more identical units of the same products or services are sold at different prices, either to the same buyer or to different buyers. It is more often observed in sales to end-use buyers (consumers) than in intermediate-goods markets (where the buyer is a manufacturer, wholesaler, or retailer); this is because in many countries price discrimination in intermediate-goods markets is considered to be an “unfair” practice by antitrust authorities. Price discrimination is also known as “flexible pricing” or “targeted pricing.” Since they sound neutral, these alternative names are often used by the business community. Whatever it is called, however, price discrimination is nothing but a marketing technique used by a seller to generate higher profits by taking advantage of differences in consumers’ “willingness to pay” (i.e., a maximum amount that each buyer is ready to pay).

Typical examples of price discrimination include student discounts for motion pictures and quantity discounts in shopping malls. Other than these obvious examples, however, judgment is often required in deciding whether or not a particular pricing practice should be classified as price discrimination. For instance, a difference in the total price of a delivery is usually not considered to be price discrimination if it simply reflects a difference in transportation costs. Goods sold at different places at different dates give different utility, and they are therefore considered to be, to some extent, different goods. A less trivial example is a pricing practice for tiered classes in airplanes. This may be seen as product differentiation if one emphasizes that passengers in different classes actually enjoy differentiated goods (e.g., spacing, meals). In this case, however, the main part of the good is the flight itself, and it may be that the carrier simply wants to engage in price discrimination. The apparent product differentiation might therefore be of secondary importance. A similar practice is found in the way publishers sell a book. Many books are initially sold in hardcover editions, with a less expensive paperback edition being published at a later time.

To discriminate in pricing, firms must obviously have some control over the price that buyers face. This situation occurs when market competition does not drive the
price down to a level at which a firm (i.e., a seller) considers exiting from the market because buyers are somehow “stuck” with particular sellers, either because it is too costly to look into all of the other alternatives, or because the number of firms in the market is so small that competition is not fierce. In addition, the cost of immediate resale among consumers must be impossible; otherwise some consumers will be better off buying the good at a lower price from other consumers (this behavior is called arbitrage).

A common taxonomy of price discrimination, contrived by Arthur C. Pigou in 1920, is based on how a firm sorts buyers, each of whom potentially has a different value of willingness to pay (i.e., a different maximum amount that each buyer is ready to pay). In first-degree price discrimination (also known as perfect price discrimination), a firm captures the entire amount of each buyer’s willingness to pay. In reality, however, this type of price discrimination is rarely observed, because the firm needs to know exactly what each buyer’s willingness to pay is, and this requirement is difficult to meet. Yet sellers may still have some idea of how many buyers there are for each particular level of willingness to pay. In second-degree price discrimination, a firm, by utilizing information on buyer preference, offers various pricing options, letting each consumer self-select into a different pricing schedule (e.g., quantity discounts or the aforementioned bookselling options). In third-degree price discrimination, the seller uses observable signals (e.g., age, occupation, location, time of use) to categorize buyers into different segments, and each segment is given a constant price per unit.

However, the boundary between second- and third-degree price discrimination is not absolute. For example, with price skimming (or behavior-based price discrimination), in which a firm offers different prices depending on a buyer’s history of past purchases and other behaviors (e.g., how often he or she has visited the firm’s Web site), a buyer usually faces a constant price for each product, while a different buyer may pay a higher or lower price depending on his or her behavioral history. Thus, price skimming does not fall within the three main types of price discrimination. Advances in information processing technology, such as the widespread use of the Internet, have made this type of price discrimination possible.

Firms are usually happy with discriminatory pricing as long as it does not make price competition too fierce. Since firms extract more of a buyer’s willingness to pay by price discrimination, a question arises as to whether buyers are always worse off than they would be with uniform pricing (when a seller offers an identical price to every buyer). Economists do not have a definite answer to this question. One instance of third-degree price discrimination that could benefit buyers as a whole, or in which every buyer could be better off, is when firms sell a good to consumers who would not purchase it under uniform pricing. In addition, as Takanori Adachi (2005) points out, with goods such as information or communications, where “network effects” are prevalent (that is, as more people buy the good, their willingness-to-pay increases), price discrimination has greater potential to improve consumer welfare. This is because a firm utilizes price discrimination to create more gains from the network effects, which can also benefit the buyers more than the amount a firm extracts from consumers’ willingness to pay. In studies combining formal modeling and data analysis, Eugenio J. Miravete (2002), Phillip Leslie (2004), and others have scrutinized the welfare effects of price discrimination. Miravete studied optional calling plans (a variant of quantity discounts) in the telephone service industry, and he concluded that the experimental introduction of optional calling plans might have harmed not only consumers, but also the telephone service company. Leslie investigated the welfare effects of both second- and third-degree price discrimination in the world of musical theater. He found that price discrimination increased a producer’s profits by 5 percent, while the loss in consumer welfare was negligible. As these studies show, there seems to be no general answer as to whether discriminatory pricing per se harms the buyer, and the question must therefore be considered on a case-by-case basis.

DISCRIMINATION, RACIAL

The word *discrimination* is derived from the word Latin “discriminare” translated as to “distinguish between.” Racial discrimination, as a commonly accepted construct,
is conceptualized as distinguishing in an unequal or less favorable manner an individual or institution by another individual, institution, or other entity with power to influence outcomes based on the perceived race, nationality, ethnicity, or national origin of the victim. It can occur as an overt action or in a subtler, covert manner.

OVERT AND INDIRECT DISCRIMINATION

Overt racial discrimination occurs when there is an illegal and direct link between an individual's perceived race, nationality, ethnicity, or national origin, or an organization's perceived characteristics and composition, and a particular negative outcome or pervasive disadvantage. Notably, the conceptualization of overt racial discrimination emphasizes the inappropriate reliance on fallible perceptions of another person's race or ethnicity as an estimate of their more general characteristics, skills, abilities, or worth. Consistent with the historical use of the word *race*, contemporary racial discrimination occurs when external characteristics such as skin tone are used as a mechanism for negative appraisal or social or political classification (Goodman 2000). Appropriately or not, race is commonly used to distinguish groups of people according to their ancestry and a more or less distinctive combination of physical characteristics. *Ethnicity*, a term that includes biological, behavioral, and cultural characteristics, is commonly used to describe groups of people with a common history, ancestry, and belief system. Because terms of categorization such as *race* and *ethnicity* are used to quickly appraise and then give meaning to individuals in our environments, they are also principle agents for overt overestimates of knowledge about an individual, group, or organization, and may facilitate inappropriate judgments and social outcomes.

Indirect racial discrimination has existed throughout the history of mankind but has only recently come to the attention of social and medical researchers. The essence of indirect racial discrimination is that a structure or policy that was designed without specific attention to race or ethnicity results in disadvantage and or detriment to a particular group of people based on race or ethnicity. One example is a policy that for security purposes prohibits a particular type of uniform, dress, or head dressing that is the normal uniform, dress, or head dressing of a particular group of individuals of similar racial composition or ethnic heritage. Other examples include the forced participation of school-aged children in a particular celebratory custom or ritual that is incongruent with the religious beliefs or customs of a particular racial or ethnic group of people.

These examples highlight several important factors about overt and indirect racism. The first is that in the context of the multifactoral dimensions of humanity and the multiple characteristics that unite and distinguish individuals (e.g., age, gender, socioeconomic status, etc.), it is sometimes difficult to prove that a single characteristic such as race is the basis of a negative appraisal or outcome. Secondly, inherent in the construct of racial discrimination is the presence of a power differential such that benefits or gains are withheld from deserving or entitled individuals or entities. In the absence of a power differential or a negative consequence, racial discrimination cannot exist.

Based on the complex definitions of race and ethnicity, racial discrimination is sometimes difficult to identify. For example, the existence of racial discrimination is not dependent on the volition of the perpetrator; it can exist even when the (accidental) perpetrator's intentions were honorable. Additionally, in some cases the negative impact on or consequences to a victim may be difficult to identify.

Racial discrimination can occur as a single event or as a more systemic and engrained intentional or unintentional policy. In cases where there is an established pattern of inequity based on race, ethnicity, or culture perpetrated by a definable individual, overt racial discrimination is usually easier to prove, but when it is a single occurrence at issue, or the perpetrator is a system or institution, discrimination may be difficult to document and prove.

CONSEQUENCES OF DISCRIMINATION

Recent evidence presented in the *American Journal of Public Health* indicated that people who experience daily discrimination may be more susceptible to a variety of health problems, including cardiovascular and pulmonary disease and chronic pains (2006). This study was notable because it was the first to explore such issues in a sample of 2,100 Asian Americans, a population traditionally thought to be insulated from negative discriminatory experiences. Similar evidence predicted poor mental health outcomes in black and Latino immigrants who were subject to racial discrimination (Gee et al. 2006). Gary Bennett and colleagues (2005) found that minorities who perceived greater amounts of racial or ethnic harassment were more likely to use tobacco daily, and ultimately may manifest greater risk of tobacco-related morbidity and mortality.

Title VII of the Civil Rights Act of 1964 was passed to protect an individual's right to employment without negative consequence or discrimination as a function of his or her race, color, national origin, sex, or religion. Title VII applies only to employers with more than fifteen employees. Current laws and regulations prohibit racial discrimination that results in differences in recruiting, hir-
ing, determination of salary and fringe benefits, training, work assignments, promotions, transfers, disciplinary actions, firings, and retaliation. Yet, the workplace remains one of the most fertile settings for claims of racial discrimination. Each year from 1997 to 2006, more than 26,000 race-based discrimination charges were filed in the United States (U.S. Equal Employment Opportunity Commission 2007).

SOCIAL AND ECONOMIC EXPLANATIONS
Beyond individual level explanations, economic models have been posited for many years to explain inequity and racial discrimination. For example, Milton Friedman, a Nobel laureate and professor who was often referred to as the “economist’s economist,” was a strong advocate of personal liberty and freedom. Among his many lifetime achievements and controversial theories were ending mandatory licensing of doctors as well as ending social security as an unfair and unsustainable system exemplary of governmental intervention in a free market economy.

In a manner consistent with his previous writings, Friedman also indicated that market racial discrimination and market competition were antithetical. More specifically, that social and political freedom was maximized and racial equality was best achieved by minimizing the interventional and regulatory role of the government, and that free markets and their associated economic forces would facilitate a state of equilibrium and fairness to all who participated (Friedman and Rose 1962).

Certainly, not all social scientists and economists agreed with Friedman. From a sociological and spatial perspective, many argued that there was a positive relationship between the size of a racial minority and discrimination. More specifically, that market competition encouraged racial discrimination. As the relative size of a racial or ethnic minority group increases, motives for the majority racial population to discriminate against the minority population may also increase toward the reduction of market racial competition and reducing threats to the loss of jobs and other essential scarce resources (Blalock 1967).

The relationship between the size of the minority population and the magnitude of discrimination is imperfect, at best. For example, the more effective the discriminatory economic practices against minorities, the less threat there is to perceived or real resources and, consequently, the less the need for discriminatory practices. In contrast, ineffective discriminatory practices promote the use of additional or more potent attempts to regulate racial competition and preserve resources of the majority. Adjustments to the marketplace mobility and economic growth of minority and majority populations is designed to preserve majority resources, particularly in the upper echelons of status, while maintaining incentives for the minority racial populations to remain engaged in such a limited and punitive system (Reich 1981).

The compelling logic of this socioeconomic model of discrimination is that the more prominent minorities are in a labor force equally accessible to majority and minority populations, the worse their ultimate economic position at the hands of the majority. Secondly, that a ceiling of economic achievement and mobility will be imposed and maintained by the majority population to preserve economic status and resources as a function of the degree to which minority racial populations are perceived as threatening. Lastly and particularly, for example, in the U.S. market, discriminatory practices against minorities will most likely persist due to the increasingly large number of minorities in the workplace and their perceived threat to the economic existence and stability of the majority unless there are regulatory and other governmental remedies.

OTHER FORMS OF RACIAL DISCRIMINATION
There are several marketplace and non-marketplace forms of racial discrimination. For example, statistical discrimination is unfair or unequal treatment of a racial group because of stereotypes or generalized estimates of group behavior or assumptions about an individual within a group based on the “average” estimated behavior for that group (i.e., greater interest rates for home mortgages for African Americans due to perceptions of greater risk of loan default). Customer discrimination refers to the process by which the racial composition of customers of a direct-public-contact business influences the race of who is hired as an employee. Although customer discrimination occurs in businesses that serve white and black customers, this practice appears to result in some reduction in overall labor demand and wages for blacks (Holzer and Ihlanfeldt 1998).

Social discrimination is the process by which non-meritorious judgments are made and differential treatment is given based on estimates of lower social status or lower social class of an individual secondary to their race or ethnicity. Governmental discrimination, like any other form of racial discrimination, is committed by governmental personnel or in a government setting against an individual based on their race or ethnicity. This can be manifest as direct actions against an individual or as policies that negatively effect groups of individuals. The difficulty of defining and then distinguishing racial discrimination from other concepts such as “preference” or “choice” is highlighted by non-market forms of private discrimination. An individual, based on previous experi-
Discrimination, Statistical

ences, social norms, or preferences can decide to exclusively pursue or exclude members of a group for mate selection. When is preference for a race elevated to the level of racial discrimination? Is this form of private discrimination harmful? Who gains and, if anyone, who is disadvantaged by such actions? Answers to these types of questions are as varied as the individuals who attempt to answer them.

CONCLUSION

In the context of a growing list of psychological and physical morbidities associated with racial discrimination, and what appears to be consistent numbers of claims of discriminatory acts each year, there remains a robust interest in factors that influence equity of processes and outcomes. Some theories suggest that racial discrimination is pathological and is to be remedied with policies and regulations. Others suggest that marketplace factors should produce a form of equality and that there is no role for government in facilitating equality of process or outcomes. Independent of theoretical orientations for resolving racial discrimination, its economic, social, interpersonal, psychological, and physiological consequences are not in question nor is the degree to which it demoralizes its victims.

DISCRIMINATION, STATISTICAL

Received economic theory of the firm admits only one motive: profit maximization. The received theory of the market is that it is most efficient when operating unconstrained. If this is so, hiring policies should seek to assemble the most efficient workforce, disregarding irrelevant factors, which cause loss due to the failure to employ the most competent available workers. (This assumes choice between candidates; namely, some unemployment. But the minimal level, often called friction unemployment, should suffice.) Despite the received theory, discrimination is rampant in recruitment against women and members of minority groups (Bertrand and Mullainathan 2004). By the theory of the firm, entrepreneurs should prefer the more productive workers over the better qualified ones, but they do not. (Even ignorance suffices to insure this; see Altonji and Plerret 1997.) This is amenable to statistical tests that may be viewed as empirical tests of the received theory. Also, it signifies discrimination being a burden on the economy. It looks as if data easily refute the received theory. It is possible to save it from refutation by two different claims. First, the perpetrator of discrimination is not the employers but, say, the employee orga-
nizations (the incumbent hypothesis). If so, then the theory is not refuted because it is inapplicable, as the (employment) market is not quite free. Advocates of received theory will not admit this defense; they will not suggest that the theory is inapplicable, at least not in the West. If the theory is applicable and is correct, then discrimination is profitable after all, even if it is disguised (Sattinger 1998). If one does not take the theory on faith, it is necessary to learn how discrimination can be profitable.

This problem concerns both the theory of the firm and the theory of the market. First, how does employment discrimination raise profits? Second, does the market mechanism operate optimally without the aid of antdiscrimination legislation? Since, admittedly, employment discrimination is clearly detrimental to the economy, the question is: Will it disappear faster with or without the aid of legislation? By the received market-mechanism theory, legislation against employment discrimination is harmful. Evidence suggests that at times this is so and at times not (Loury 1981; Neumark and Stock 1999). Hence the received theory of the market needs adjustment to allow for some government intervention. (This is scarcely news, since even the most ardent defenders of received theory do not oppose systematic monetary interventions, not to mention fiscal ones.) Does the same hold for the received theory of the firm?

Possibly, discrimination has a cost, and it should be considered a part of entrepreneurs’ preference. Their preferences thus become a part of the theory of consumers’ preference (Swinton 1977). This is a serious deviation from received theory that takes the theory of consumers’ preferences as no more than a theoretical nicety, since the market tends to aggregate demand only (Agassi 1992). The option left for the effort to rescue the received theory of the firm, then, is to explain how discrimination incurs no loss.

One explanation holds that discrimination is economically advantageous because it pleases community leaders, especially in underdeveloped countries where it is socially obligatory. This explanation interests students of business public relations and voluntary organizations such as the United Nations Volunteers and others who attempt to improve matters. Economists tend to ignore this view, since obviously not all countries maintain free markets. This is regrettable, since market freedom is a matter of degree. Economists tend to declare deviations of the market from received economic theory insignificant, praise the market for the advantages of modern liberal society, and blame deviations from it for the disadvantages. According to a second explanation, discrimination is due to employers who cling to refuted views as prejudices. This explanation does not help received economic theory that deems the market mechanism the best means for eliminating inefficient entrepreneurs through competition. A third explanation holds that the advantage of discrimination is in its reduction of the cost of hiring, since members of the preferred groups keep their jobs for longer periods. Such advantages are called statistical discrimination. Not surprisingly, this view of discrimination is pivotal (Collinson et al. 1990), and so it deserves attention. Is the hypothesis true that discrimination is advantageous?

Before examining the hypothesis we should ask the following questions: (1) Does it rescue the theory? (2) Does it suggest that the market mechanism still is the best way to overcome discrimination through recruitment? (3) Does it suggest leaving matters to the market mechanism anyway?

The theory allows for statistical discrimination only if it is cost effective. If so, then reducing the influence of discrimination on workers’ turnover should reduce it. Even then, allowing for statistical discrimination cannot be the best strategy, because reducing it by legislation is an improvement, even from the strictly economic viewpoint. Defenders of the received theory are familiar with such criticism, and do not deny it: certain legislations may outdo the market mechanism, but these are too costly and their advantages are temporary at best. In the long run, the market mechanism is the most efficient means for tackling social evils. This response is a reading of received theory as promising social benefits only in the long run.

To this view, John Maynard Keynes (1883–1946) responded with his memorable adage: in the long run we are all dead. This means that we cannot test this version in a lifetime. Moreover, the evils we are facing are pressing, and the promises of received theory are postponed and doubtful. This is still under debate, however, especially since statistical discrimination is less pressing than the massive unemployment that troubled Keynes. The central question then is: Is the statistical discrimination hypothesis true? We do not know. Is it at least testable? If not, should we give the market mechanism the benefit of the doubt or should we fight discrimination or wait for the market to do it? Waiting is questionable, since pockets of poverty and related ills are stagnant, and, notoriously, many social factors hardly benefit from the economy, which adds to the stagnation. Instances for this are understandable but intolerably self-reinforcing: the disposition of the police to seek criminals within the groups in which crime prevails, persistent poor education, under age pregnancy, and the absence of intergenerational mobility where it is needed most. The self-reinforcing of socioeconomic patterns ensures social stability at the cost of retaining various social evils, employment discrimination included.

The opinion that the market mechanism is the best means for the eradication of social ills is questionable.
Opposing laws against discrimination requires particularly strong arguments. Arguing that such legislation is ineffective will not do: many laws are ineffective yet we still want them on the books. The paradigm case is the proscription of statutory rape by minors. The argument against the proscription of discrimination is therefore understandably philosophical. In principle, advocates of the market mechanism theory approve only of laws that are essential for the maintenance of the market. Thus, they approve of imposing the honoring of contracts, but not truth in advertising; the market can live with false advertisements and the market mechanism will eliminate them, they say. Even if we accept this kind of argument, advocates of the market mechanism theory cannot show that the market tolerates no social ills that are too objectionable. As discrimination is both objectionable and a burden on the market, and since laws against it are no burden on any social group, the theory of statistical discrimination is a priori too feeble—apart from its dependence on many questionable assumptions. Which is not to say that we need not test these assumptions: they may be interesting for other ends, especially as means of insight into the costs—economic and other—of social stability. As Karl Popper (1902–1994) suggested more than half a century ago, however advisable it is to rely on the market mechanism when it works, the view that it always works well is a metaphysical dogma. This squares with his proposal to replace the demand for social stability with the demand for democratic controls.

DISCRIMINATION, TASTE FOR

A person (an employer, coworker, or consumer) is said to have a taste for discrimination if he or she would pay to maintain social or psychological distance from members of a particular group. A related concept, nepotism, is used to describe a sacrifice of income to maintain proximity to members of a particular group. A taste for discrimination is, in this analysis, no different from having a taste (preference) or distaste for any market commodity. This approach to discrimination was first articulated in *The Economics of Discrimination* by economist Gary Becker. Since publication of this pioneering work in 1957, Becker’s analysis has become the dominant theory of discrimination within mainstream economics.

Becker claimed that the motivations behind discriminatory tastes were the province of sociologists and psychologists. His stated objective was to focus solely on the economic consequences of discriminatory preferences translated into economic behavior. He explicitly considered, however, the motivations to be nonpecuniary. According to Becker, one actually discriminates, as opposed to merely having a taste for discrimination, when one forfeits income in order to indulge this preference. The employer who hires desirable workers pays relatively higher wages and is content to do so. Costs of production increase and therefore diminish profits. Conversely, a nondiscriminating employer—should one exist—will hire the workers with the lowest market wages if they are no less productive than members of the desired group.
According to Becker, uninhibited market forces should punish discriminators whose businesses are less profitable. If the industry is not competitive, however, employer discrimination may be able to persist for a longer time.

Customer discrimination, in contrast, is not subject to the same market discipline. So long as the customer is satisfied with paying to indulge his or her taste, the status quo can continue. Employees’ taste for discrimination manifests as a desire for higher wages to compensate for working alongside the undesired group. To avoid such costs, employers can segregate jobs.

The assumption that discrimination is not profitable has important policy implications. Mainstream economists have utilized Becker’s model to argue that market competition undermines discriminatory practices, and therefore antidiscrimination regulations are unnecessary. Persistent wage differentials are deemed to be due to productivity differences alone, rather than discrimination. In a 1998 review of empirical research in the *Journal of Economic Perspectives*, however, William Darity Jr. and Patrick Mason note that multiple methodologies have revealed ongoing discrimination. Similarly, Francine Blau and Lawrence Kahn (2000), in the same journal, summarize a range of studies on the gender pay gap and find ongoing evidence of discrimination despite women’s increased acquisition of human capital.

Theories that blur the boundaries between in-market and premarket discrimination, as well as those in which market power is viewed as a normal result of competitive processes, better explain why wage differentials can persist and be profitable, according to Darity and Mason. The core assumption of Becker’s model is that the preference to associate (or not associate) with people with specific ascriptive characteristics is exogenously given. Nonpecuniary motivations imply a lack of economic incentives to discriminate. This assumption has long troubled political economists focusing on institutionalized discrimination (D’Amico 1987). For political economists, discrimination is endogenous to economic processes (Mason 1995; Shulman 1996). First, employers benefit from discrimination via *class struggle effects* by perpetuating divisions among social groups, discrimination “divides and conquers” the workforce by limiting worker organization. Second, *exclusion effects* or *job competition effects* imply that members of dominant groups who get preferential access to labor market queues have economic incentives to maintain these hierarchies.

Research by anthropologists, psychologists, and other social scientists indicates that race-ethnicity, sex-gender, and other social categories do not have intrinsic meaning apart from specific social contexts. The process of forming such identities is therefore complex. Treating discrimination as a “taste” presumes that the meanings of such ascriptive characteristics are generated outside of economic processes rather than examining how racial (or gender) identities become “productive property” (Darity et al. 2006, p. 302). Members of privileged groups develop property rights in their racial and gender identities, according to a game-theoretic model developed by Darity, Mason, and James Stewart (2006). In their model, as well as in the historical examples they cite, taking on a racialized identity, as opposed to an individualist mindset, garners concrete benefits. Such identities provide access to income and wealth for group members, making them intransigent over time. Their conception of identity contrasts with the primarily ideological and cultural depiction of identity in George Akerlof and Rachel Kranton (2000); their model discounts the prevalence of discrimination by emphasizing the voluntary choices made by women and others to eschew occupations and economic activities associated with dominant groups.

According to Deborah Figart and Ellen Mutari (2005), Becker’s focus on preferences for social distance draws upon the prevailing discourse about racial segregation in the 1950s United States, but it is not a universal theory of discrimination. Impersonal entities such as corporations, for example, do not have a desire for distance. Other forms of discrimination defined out of the scope of Becker’s analysis, including wage discrimination and *statistical discrimination*, have complex but different dynamics. In fact, forms of discrimination may evolve in response to changes in the political economy (see Darity and Mason 1998; Blau and Kahn 2000). Taste for discrimination, therefore, is at best a partial explanation of labor market practices.

Darity, William A., Jr., Patrick L. Mason, and James B. Stewart. 2006. The Economics of Identity: The Origin and
Wage discrimination occurs when, due to the operation of the labor market, similar workers receive different wages on the basis of race, sex, ethnicity, age, sexual orientation, or other ascribed characteristic not directly related to productivity. Workers subject to wage discrimination may earn lower wages in a given job, be assigned to low-wage jobs within firms, or employed in low-wage firms.

Not all wage differentials are discriminatory. If more group A than group B workers are willing to work in dangerous but highly paid jobs, on average, As may earn more than Bs do. But provided that wages are based on the nature of the job and not group membership, the wage differential need not reflect wage discrimination. Similarly, if As are paid less because they are less skilled, there is no wage discrimination unless their lower skills reflect their expectation that their skills will not be rewarded.

MEASURING WAGE DISCRIMINATION
We rarely measure worker productivity directly and, therefore, we cannot test whether equally productive workers earn different wages based on their group membership. Instead, we ask whether apparently similar workers of different races, sex, etc., receive different wages. The difficulty with this approach is determining the dimensions along which workers should be similar. For example, suppose we compared men and women with undergraduate degrees in biology and found that women have lower wages. Suppose we also found that for those of this group that are teachers, wages are similar for such men and women. We might conclude that many women choose to be teachers, perhaps in order to be with their children after school and during vacations. Women (and men) with these preferences accept lower wages, so there is no wage discrimination. However, perhaps women face significant wage discrimination in jobs outside teaching, so that those who do not teach are the very talented or lucky few who find high-wage jobs outside teaching. In this case, we miss the wage discrimination by comparing men and women in the same occupation.

Moreover, if firms discriminate by offering low wages to, for example, African Americans, individuals offered these low wages may respond by not working, and we will only observe wages for those African Americans employed at good wages by nondiscriminating firms. Ignoring individuals who are not working underestimates the black-white wage differential and thus the extent of wage discrimination.

Estimates of the degree of wage discrimination, and even its existence, depend critically on the factors for which we control. There are large earnings differentials between men and women, blacks and whites, and non-Hispanic whites and Hispanics if we take no other factors into account. Skin-shade studies have found that darker Hispanics and African Americans are paid less than Hispanics and Africans with lighter complexions. Controlling for cognitive test scores in high school eliminates much of the difference between black and white men, but a significant difference reappears if we also control for years of education. Differences in the earnings of black and white (employed) women are modest, but are much larger if we take account of the potential earnings of nonworkers. Much of the Hispanic–non-Hispanic wage differential can be “accounted for” by education and by knowledge of English. Career interruptions are important in “explaining” female-male wage differentials.

THEORY
In his pioneering work The Economics of Discrimination (1971), Gary Becker argued that labor market competition will eliminate wage discrimination. If, for example, blacks are paid less than are equally productive whites, unprejudiced employers will hire blacks and make more profit than do employers who hire whites. Nondiscriminating firms will expand, hire more blacks, and drive some discriminating firms out of business. The process continues until black and white wages are equalized. Some discriminating firms that hire only white workers may survive, but there will be no wage discrimination. Similarly, if workers discriminate by requiring a premium to work with blacks, they will be employed in segregated firms, but wages will not depend on group membership.

This conclusion must be tempered somewhat if customers are prejudiced. In this case, blacks will work in jobs where race is invisible and, if there are enough such jobs, receive the same wages as comparable whites.

References

However, in areas such as professional sports, where workers have highly specialized skills and race is clearly visible, wage discrimination may persist.

If labor markets operate less smoothly than the competitive model implies, through a variety of mechanisms they can exacerbate, not eliminate, the effect of prejudice. For example, firms that announce high wages to attract many applicants may deter black applicants who anticipate losing out to white applicants. Instead, blacks may apply to low-wage jobs in order to avoid competition with whites. Wage discrimination may also persist if workers and firms act collectively and wages are governed by bargaining. Workers may coalesce to exclude those who are “different,” and firms may pay lower wages to those with less bargaining power.

Other models also permit persistent wage discrimination. In social distance models, interactions between heterogeneous groups are costly. The market minimizes such interactions and thus encourages segregation, but complete segregation is impossible. Members of subordinate groups must either adopt the dominant group’s norms of behavior and social interaction or accept lower wages.

Social distance and the absence of shared networks may also reduce the ability of employers to evaluate potential employees from other groups. In this case, employers may engage in statistical discrimination, whereby they rely more on group membership and less on information about the particular individual. Such workers have less incentive to make unobservable investments in themselves (e.g., work hard in school) and thus will earn less than do observably similar workers whom employers evaluate individually. However, they may also have an incentive to make more observable investments (e.g., years of schooling). Similar mechanisms apply when statistical discrimination reflects self-confirming stereotypes rather than social distance.

**POLICY**

In the United States the Equal Pay Act of 1963 outlawed payment of different wages for the same job on the basis of race, but this had little effect because most wage discrimination probably arises through workers holding different jobs and working in different firms. The 1964 Civil Rights Act forbade employment discrimination based on race, ethnicity, sex, or religion, and Executive Order 11246 required federal contractors to take affirmative action to ensure that they did not discriminate on the basis of race. Over time, the scope of civil rights legislation in the United States has been extended so that it covers, in various degrees, age, disability, and sexual orientation, as well as race, ethnicity, sex, and religion. Many countries have similar laws. Although most analysts believe that these policies reduced wage discrimination against African Americans, women, and other groups, the extent of the effect is hotly debated.

**DISCRIMINATION, WAGE, BY AGE**

The differential treatment of a group based solely on the grounds of chronological age is known as age discrimination. Unlike race and gender, age is immediately and strongly tied to experience and future job tenure. In addition, a worker can age while still in the same job, whereas changing one’s group is unlikely for women and racial and ethnic minorities. Problems of age discrimination are important from a policy standpoint because many older people are able to work longer than was the case with previous generations. Many also wish to work longer, while some may not have saved adequately for retirement. A number of plans to fix Social Security budgetary problems require continued work at older ages.

Employers can discriminate by age across several areas: wages, promotions, hiring, firing and layoffs, and forced retirement. On average, older workers make more money than younger workers because age is highly correlated with both general labor-market work experience and tenure (or longevity of employment) at a particular employer, and experienced workers generally make more money than inexperienced workers. It is difficult to disentangle the effects of age from experience. Older workers may be less likely than younger workers to accept employment at lower wages because they are used to being paid higher wages based on their experience. Promotion probability is also related to experience. Older workers are less

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 401
likely to be hired or fired than younger workers, but they are often removed through retirement packages.

Not much is known about group differences in age discrimination. Some studies have found that women are affected by age discrimination at an earlier age than men, but others have found no difference between genders in this regard. Even less is known about differences in age discrimination by race. Group characteristics of the person doing the potential discrimination, such as age, race, and gender, among others, also determine the presence and extent of discrimination.

There are a number of reasons that employers could discriminate against older workers. Employers may irrationally dislike older workers, employees may dislike working with older workers, or consumers may dislike buying products and services provided by older workers. This irrational dislike is also known as animus or taste-based discrimination. Although Gary Becker’s models of taste-based discrimination in a competitive market for race and gender can be used to model age discrimination, they are limited by the correlation of age and returns to experience in most jobs in the real world, and by the fact that workers age while employed. No evidence has been found for taste-based discrimination against older workers.

Employers could also discriminate against older workers because of incorrect stereotypes, and because, on average, older workers may be less productive or more expensive than younger workers, causing employers to be reluctant to hire them when there are screening costs. This type of differential treatment is termed statistical discrimination. When asked why other companies may be reluctant to employ older workers, human resources managers cite shorter career potential; lack of energy, flexibility, or adaptability; higher costs for benefits and salary; more health problems, leading to more absences; knowledge and skills obsolescence; a need to promote younger workers; suspicions that an older worker might leave his or her current job to retire; and fear of discrimination lawsuits. Many of these reasons support either the incorrect stereotypes hypothesis or the statistical discrimination hypothesis.

Age discrimination against workers over the age of forty is prohibited by the Age Discrimination in Employment Act (ADEA) of 1967/68, which prohibits discrimination in advertisement, hiring, promotions, and firing, except in cases where there is a Bona Fide Occupational Qualification (BFOQ). A BFOQ is allowed if the job requires a member of a certain group to perform it. For example, in a movie, the studio would be allowed to advertise for and hire a young white woman to fill the part of a young white woman. With age, BFOQs are sometimes allowed for safety reasons even if a percentage of older workers would be able to safely perform the job tasks. Examples of BFOQ for safety reasons include mandatory retirement for airline pilots and minimum hiring age for bus drivers and air traffic controllers.

DISCRIMINATION, WAGE, BY GENDER

Gender wage discrimination occurs when employers pay women lower wages than identically qualified male workers. Whether such employers are acting on their own preferences or those of their firm’s owners, managers, employees, or customers, the unequal treatment of women violates norms of equity and considerations of market efficiency and is the subject of policy research and debate in most industrial countries.

Theorists populate the demand side of labor markets with employers who must choose whom to hire and how much to pay them relative to the value of their productivity. Assuming that firm owners and their agents are eco-
nomically rational and that they must accommodate the wishes of all firm constituents, paying qualified women a wage that is less than their productivity’s worth while paying men the value of their productivity must optimize profits. Thus Gary Becker (1971) argues that an employer’s choice to discriminate against a particular group can be economically rational but can persist only under noncompetitive product market conditions.

The larger the number of firms competing with a discriminatory employer for male workers, the higher the premium in pay men can garner. However, the larger the number of firms competing with an employer for customers in its product market, the more difficult it is for an individual employer to maintain its discriminatory behavior: competitors who are more willing to hire women (and pay them better than the discriminatory employer) will have lower labor costs and the ability to charge lower prices in the product market. Though the theory is compelling to many, the notion that product market competition (as opposed to antidiscrimination labor market policy) reduces wage discrimination has not been proven empirically and fails to explain the persistence of wage discrimination by gender.

As pointed out by Becker (1998), economists view the supply side of labor markets as populated by workers who choose to equip themselves in specific ways for the jobs available to them. Because average worker characteristics differ by gender, women’s choices about education, training, working hours, and number and length of job interruptions (along with socialization by teachers and parents) are often blamed in part for women’s overrepresentation in some fields and scarcity in others. The larger the share of women among the unemployed in a particular market, the greater the need for women to compete for scarcer opportunities—offering their services for lower wages and benefits than would otherwise be necessary.

Barbara Bergmann (1986) has shown that if the discriminatory barriers were removed, women’s wages would rise relative to the wages of men. Scholars debate the extent to which discriminatory employer practices versus women’s own choices bar women’s access to jobs in some markets and crowd them into others. This is not a particularly productive policy debate, however. It sidesteps the most relevant policy questions: How do we reduce the ability of gender norms, employers, and markets individually and collectively to limit women’s participation in specific occupations? How do we prevent employers from paying qualified women less than their male counterparts when they do choose the same industries, occupations, hours, and other labor market characteristics (a problem convincingly documented in Blau et al. 2001).

Gender wage discrimination persists as women are systematically denied access to jobs in particular markets. Scholars such as Kenneth Arrow (1973) attribute persistent labor market discrimination to statistical discrimination—employers ranking and paying individual applicants according to average gender group attributes rather than individual ability and productivity. Statistical discrimination is sometimes deemed economically rational because information about individual worker productivity is costly and difficult to attain. Such discrimination persists because gender norms and stereotypes are powerful and because firms’ discriminatory practices are difficult to detect and prove. As explained by Lisa Saunders and William Darity Jr. (2003), wage discrimination by gender is further complicated by the fact that the degree of gender wage gaps differs according to the race, age, sexual orientation, and other identity markers of the female or male groups under consideration. The maintenance of social stratification on the basis of multiple identities insures lower wages for a significant share of workers than would otherwise attain more (see Darity et al. 2006). This is especially problematic for workers in competitive firms and more onerous under conditions of globalization. It is also problematic for families that increasingly depend upon women’s earnings for their immediate and intergenerational economic security. It could be argued that a more effective policy approach to wage discrimination by gender would assert a definition of discrimination that acknowledges the complex ways it actually manifests in labor markets, a perspective on the roles played by structural changes in the global economy, and a rigorous analysis of wage inequality’s effects on inequality in wealth.

Darity, William, Jr., James Stewart, and Patrick L. Mason. 2006. The Economics of Identity: The Origin and Persistence of
Wage discrimination refers to paying women, minorities, or other culturally subordinate individuals lower wages than comparably skilled men, whites, or other privileged groups. This can happen when women or minorities are hired or promoted into lower-paying jobs, or when they are paid less for performing the same work in the same workplace.

In general, past research has found that wage discrimination increases with the rank of the job. Thus, the term rank segregation is sometimes used to indicate that job segregation by status is associated with job desirability. Most common have been analyses that demonstrate race and sex wage gaps after controlling for legitimate measures of individual productivity, such as education, experience, or job skills. These studies typically find that most wage inequality is produced by job segregation, though in some contexts there may be additional discrimination in wage setting within jobs. The more desirable the job, the more likely it has within-job wage discrimination and the more likely that women and minorities are excluded from the job.

Employment discrimination and job segregation are the product of a series of well-recognized selection and evaluation mechanisms, such as prejudice, cognitive bias, statistical discrimination, social closure around desirable employment opportunities, and network-based recruitment. These mechanisms tend to be mutually reinforcing and lead to status expectations about the appropriateness of different types of people for different jobs, as well as to expectations as to the value of those jobs to the employer. Bias in evaluation processes, which in turn may lead to between- or within-job wage inequalities, can result from self-conscious prejudice, but it is often produced by subtle social psychological processes of cognitive bias, stereotyping, and in-group preferences. Employers, like everyone else, tend to use preexisting cultural categories such as sex or race to organize and interpret information. These cognitive processes can lead to more favorable evaluations and outcomes for high status individuals (males, majority race) and lower evaluations for others (women, minorities). The theory of statistical discrimination points out that employers are more likely to discriminate when jobs have more responsibility, longer periods of training, or simply pay more, because the cost of hiring an unqualified worker rises in these situations. Economists tend to describe this process in terms of explicit cost-benefit calculations. Sociologists and psychologists see this as a more subtle social psychological process of cognitive bias and stereotyping.

The term social closure refers to discrimination around the preservation of group privilege. Social closure processes are consistent with the discriminatory mechanisms already outlined—prejudice, cognitive bias, and statistical discrimination. They are not merely conditioned by individual psychology or the profit motive, however, but also by both social accountability to one’s status group and the elaboration of cultural stories that explain and justify status-based inequalities. Because social networks tend to be formed around friendship and family ties, employee recruitment procedures that rely on professional or current workforces will also tend to produce social closure-based opportunity hoarding.

**DISCRIMINATION, WAGE, BY RACE**

Wage discrimination involves differential market wage payments for otherwise identical persons. Wage discrimination may occur because of prejudice (statistical discrimination), bigotry and nepotism (animus toward other-group persons and favoritism toward on-group persons), or because it enhances profitability (racism). An early work by Francis Y. Edgeworth in 1922 considered equal work for equal pay by sex, matching the marginal utility of the employer with the marginal disutility of the employee. This concept was accepted with some reservations and adjustments. Equal work means that the worker is indifferent between two tasks, and equal pay means that wage is equal to the marginal product of labor.

Gunnar Myrdal discussed animosity of whites against blacks in the United States from the point of view of the cumulative methodology where increased prejudices caused more discrimination and less employment, worsening both standards of living and health conditions for blacks. Discrimination causes a cumulative degradation of blacks’ standard of living, education, health, morals, and social conditions.

Gary Becker’s preference theory of discrimination advanced a coefficient of discrimination, $d_i$, measured under free competition. Assuming away differences in capital, the employer’s utility function depends on profits, and the types of workers—whites and blacks. If workers are equally productive, then discrimination enters through the tastes and preferences of the employer. An employer is willing to pay a higher wage, $\pi(1 + d)$, to exclude someone from employment. An employee is willing to accept a lower wage, $\pi^*(1 - d)$, to avoid working near to someone. A consumer is willing to pay a higher price, $p(1 + d_i)$, not to be served by someone. The result is a kinked demand curve for labor if we plot the ratio of the wages of blacks to whites, women to men, young to old, or unskilled to skilled against the person discriminated against. When the ratio is unity, no discrimination happens, $d = 0$, and the demand curve is flat. The kink occurs where the wage ratio starts to fall from unity, indicating that the discrimination coefficient, $d_i$, is becoming larger. At equilibrium, the downward sloping part of the demand curve cuts a normal supply curve that measures more labor offered as the wage ratio increases. One implication of equilibrium is that since minority workers offer the same productivity at lower wages, a discriminating employer will have to pay higher wages to others.

Phelps advanced a statistical discrimination model to explain why, for instance, insurance companies price auto insurance higher for teenage males than females. Companies use the average behavior of the group and not individual characteristics in pricing their policies. Another popular model is Barbara Bergmann’s expansion and articulation of the crowding hypothesis. The productivity of minorities who are crowded into certain occupations may depend on group effort and having minorities in a group can be perceived as a hindrance to social interaction, lowering productivity and causing wages to fall. An index of occupational segregation showing by how much mobility between occupations is necessary to equalize wages has been declining over time. Other models consider different market structures.

William A. Darity Jr. and Rhonda Williams argue that governmental actions that allow free occupational choice is not sufficient to eliminate discrimination due to cultural barriers that create imperfect markets. Darity found that research studies on discrimination lack a unified methodology and that some studies that subscribe to the positive methodology find discrimination antithetical to perfect markets. However, Patrick L. Mason has presented a theoretical model and empirical analysis showing that racial wage and occupational discrimination may enhance the profitability of firms and protect dominant group workers from competition in the more desirable occupations. The theoretical analysis by Darity and Williams and Mason is constructed on the notion that racial discrimination is sustained by racism among employers and racial animus among workers. Moreover, in their discussion of the economics of identity, Darity, Mason, and Stewart show that the persistence of racial group identities, that is, the origins of the tastes for discrimination, may be found in the material incentives associated with inter-group antagonism and intra-group altruism.

Since the mid-1970s, government statistics for the United States have indicated that the wage ratio for blacks to whites has been stable indicating a large earning gap. The unemployment rate for blacks is about twice that of whites, but results are similar when comparing unemployment rates for white and black males against the rates for white and black women. For the same timeframe, the index of gender segregation (male vs. female) fell by approximately 16 percent from a high of approximately 68 percent in 1973, indicating that women have made considerable entry into professional occupations. The
index for previous age discrimination confirming racial segregation (black vs. white) shows the same trend, falling from 37 to 24 percent for women and from 37 to 26 percent for men.

DISEASE
Stedman's Online Medical Dictionary defines disease as an interruption, cessation, or disorder of body function, system, or organ; or a morbid entity characterized usually by at least two of these criteria: recognized etiologic agent(s), identifiable group of signs and symptoms, or consistent anatomic alterations. The International Classification of Disease, 9th Revision, Clinical Modification (ICD-9-CM) is one of the main texts used in the United States to identify, categorize, and diagnose disease. The Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM-IV), is used to define and diagnosis mental disorders. While these sources are used in common medical practice, it is not completely clear in the philosophy of science what truly defines the diseases and disorders that these texts classify. Some have argued that there is not a simple definition of disease. Within the philosophy of medicine and bioethics, there is not only disagreement about what a disease is but whether or not disease can be defined or whether it is necessary to have a fixed definition in order to provide care.

NATURALISM AND NOMINALISM
A simplistic yet prevailing conception of what disease is can be viewed from the lens of “naturalism” or “nominalism.” Viewed from a naturalistic point of view, disease is a real thing that can be quantified, observed, or described using the language of natural science. To the naturalist, a disease can be discovered in nature, is not invented by social convention, and is not dependent on contextual circumstance. The true naturalist views disease as value free and objective. Disease from a naturalist point of view, according to the philosopher Christopher Boorse, causes interruptions in the ability to “perform typical physiological functioning with at least typical efficiency” (Kovacs 1998, p. 31). This point of view, however, has been critiqued because “typical physiology” and “typical efficiency” cannot be objectively described, nor are they value-free terms (i.e., what is meant by “typical?”).

The nominalist point, on the other hand, views disease not as something essential in nature but rather as a
description of socially constructed conditions. As stated by Lester King in 1954, the point of view that "disease is the aggregate of those conditions, which, judged by the prevailing culture, are deemed painful, or disabling, and which, at the same time, deviate from either the statistical norm or from some idealized status" would fit within this nominalist point of view (King 1954, p. 197). Historically, a purely naturalistic view of disease as a germ or lesion has given way to a view of disease that appeals more to a nominalist point of view. Ailments that fall within modern medical health care, such as depression or hypertension, challenge a naturalistic point of view because these conditions appeal to socially defined criteria by which one would be in need of professional care or qualify for some sort of intervention.

DISEASE, ILLNESS, SICKNESS, AND HEALTH

In discussing the concept of disease, attention has been brought to how terms such as disease, illness, or sickness relate. Oftentimes these concepts have been used interchangeably. However, philosophers argue that separating the concepts may be useful. Disease is distinguished from illness in that disease is the subject matter of the medical practitioner and scientific medicine. Illness, on the other hand, explains what the person is experiencing. Sickness is what is attributed by society to individuals who conceive of themselves as ill and whom medical professions identify as having a disease. Each of these concepts justifies action. Medical professionals are charged with identifying disease, discovering diseases, and treating persons with such conditions. Persons who are ill are charged with describing the subjective experience of their condition to others who may be able to help. Society is responsible for determining the rights and duties of a person who is ill and/or diseased. Thus conceptualizing disease as separate from illness and sickness can be useful in bringing into perspective the varying roles of the medical practitioner, the individual, and society when negative bodily conditions or states occur.

The concept of disease is also often discussed as it relates to health. That is, to understand what disease is, one must know what health is. The common language conception of health is simply the absence of disease or the negation of being at ease (i.e., dis-ease). A person who is healthy does not have a disease, and a person with a disease is not healthy. However, this simplistic model may not be applicable in all circumstances. For example, a person diagnosed with hypochondriasis certainly is suffering, but the individual does not have any general medical condition that can account for his or her feeling of illness. There are also instances when one feels healthy but may have a serious condition that places the individual at risk for a disease (e.g., a person with hypercholesterolemia or obesity may develop coronary artery disease).

The holistic approach extends the more simple approach to defining health not just as the absence of disease but as a state of complete physical, mental, and social well-being. The holistic model has been adopted and promoted by the World Health Organization. The holistic model would imply that one could meet the condition of not having a specific disease but still may not be healthy. Within the holistic model, eliminating disease from the body is not primary, but rather, health is primary. However, some have argued that a holistic program of health care with the goal of insuring complete physical, mental, and social well-being is not feasible; especially in developing countries, where there are limited resources available for the provision of care.

The model most familiar to Western medicine is the medical model of disease. The medical model suggests that disease is not just absence of health (as defined by the simplified model), but disease can be identified by some set of standard methods, such as a medical examination, laboratory tests, or correspondence with a set of symptoms. Thus within the medical model a person could potentially not have an identified pathophysiological disease but could still be labeled as having a disease as a result of having a set of symptoms and being deemed not healthy through the process of a medical examination.

CONTROVERSIES IN DEFINING CONDITIONS AS DISEASE

Within modern medicine there are many controversies over what conditions can be properly defined as diseases. One such debate in the general medicine and public health has to do with whether or not obesity can be labeled a disease. George A. Bray, an internationally recognized researcher in the area of obesity and diabetes, has argued that obesity meets the criteria to be labeled a disease. However, other researchers have argued that caution should be taken when labeling obesity as a disease as it may not be appropriate to put it on par with other more serious life-threatening conditions. Those that argue obesity should not be considered a disease suggest that there are no real signs or symptoms of obesity apart from excess adiposity. However, this is circular because excess adiposity is the definition of obesity. Also, while obesity does cause impairment in functioning for some people, there are many people who are obese who have no diminished impairment in functioning. Those who argue that obesity is a disease equate it with other diseases, such as depression. Bray states that obesity involves “deranged neural circuitry responding inappropriately to a toxic environment” (Bray 2004, p. 34).
Another long-standing debate in the medical discipline of psychiatry is whether or not certain psychological conditions can be labeled a disease. A mainstream view of modern practice in psychiatry is that certain psychological conditions rise to the level of an illness when there is a clinically relevant disruption in functioning and distress. The DMS-IV distinguishes a mental pathological condition from a milder form by establishing clinically significant criterion. As stated in the DSM-IV, the condition must cause "clinically significant distress or impairment in social, occupational, or other important areas of functioning" (DSM-IV 1994, p. 7). The determination of significance is a clinical judgment made through the process of a clinical interview with the patient and sometimes with third parties, such as a patient’s family. Further, a mental disorder is often distinguished from a condition that arises as a direct physiological consequence of a general medical condition. For example, disorientation or hallucinations due to a brain tumor or stroke would not be considered a psychiatric condition.

Notably the explanation of aberrant behaviors or mental conditions has changed over the centuries. In past centuries aberrant behaviors and mental disorders were explained as the result of "spirits" or "sins." With the birth of psychoanalysis, mental conditions were explained as primarily resulting from poor child rearing or the inability of an individual to meet developmental milestones marking social and moral development. However, early twenty-first-century psychiatric practice tends to explain many psychiatric conditions as the result of disruptions in neural circuitry in the brain resulting from a combination of genetic and environmental determinates.

This change in perception of psychiatric conditions is argued to be due to an increasing scientific knowledge about potential causes and treatments. However, the psychiatrist Thomas Szasz has been a prominent critic of this traditional point of view. Szasz argues that mental disorders, as mainstream psychiatry has conceptualized, are not diseases of the brain and that it is inappropriate to call abnormal behaviors and psychological states "diseases." A crux of difference between these two points of view has to do with the way disease is defined—that is, as a "lesion" of the body or as a social construction or metaphor.

SOCIAL DYNAMICS OF DISEASE AND HEALTH INEQUALITIES

Regardless of how disease is defined, it is widely recognized that the spread of disease and the preponderance of health are linked to social factors. For instance, density and frequency of contact among individuals can influence disease outbreak. Dense social contact in urban environments may lead to a rapid spread of certain infectious diseases. Understanding the social networks and dynamics of these environments is a key strategy for developing targeted vaccinations and treatments.

Disease and health are also influenced by social and economic conditions in society. For example, in the early twenty-first century in the United States, Type 2 diabetes mellitus is more common among African American men than their Caucasian counterparts. However, a 2007 study by Margaret Humphreys and colleagues found rates of diabetes among African American men living circa 1900 to be much lower than Caucasian men at that time. Studies looking at coronary heart disease patterns have also reported prevalence shifts whereby the risk of the disease was historically more prevalent in higher socioeconomic classes and now is more prevalent in lower socioeconomic classes (Kunst et al., 1999; Marmot, Adelstein, Robinson, and Rose, 1978; Rose and Marmot, 1981). These studies highlight the fact that disease patterns as well as the social distribution of risk factors for disease can vary by type of disease, time period, and geographic region.

As disease and health are viewed as socially determined, the search for social conditions that gives rise to diseases has become a growing part of medical and public health science. Medical practice in the past centuries was focused primarily on identifying pathophysiological and biological roots for disease and had largely ignored the social contributions to disease. Correspondingly treatments and interventions for disease management have been one-to-one efforts. However, a growing awareness that societal-level phenomena play a large role in health and disease has prompted the medical community to explore some of the broader social and economic forces that influence disease and risk. As such the approach to disease management is also shifting from primarily individual-level one-to-one efforts to include environmental and policy-level interventions designed to address health.

Finding a clear definition of disease and health is not purely a philosophical matter. Conditions that carry the label of disease have practical and political implications. Society responds by directing resources, and individuals with a certain disease are relinquished from certain social responsibilities. However, what counts as disease is often difficult to determine. In some cases it might appear that a certain condition has pathophysiological roots and causes (e.g., germ or lesion) that can be discovered and treated. However, it may be discovered that there are broader social and economic conditions that allow for certain pathophysiological conditions to arise. What then is the disease? Is it the germ or the social condition? The answer that society provides becomes one of the defining features by which health care resources are allocated.

DISNEY, WALT
1901–1966

Walter Elias Disney and his brother Roy established the Walt Disney Company in the late 1920s to produce short animations. The company’s first synchronized-sound cartoon, Steamboat Willie (1928), featured Mickey Mouse, a character that became one of the best-known icons in the world. In the wake of the nineteenth-century transformation of the oral tradition of fairy tales into a literary tradition by the Brothers Grimm, Hans Christian Andersen, and others, Disney, in the early decades of the twentieth century, employed technological advances to turn literary fairy tales into animations. The first feature-length animation, Snow White and the Seven Dwarfs (1937), paved the way for the Disney brand of family-oriented celluloid fantasies targeting children as their primary audience.

A 1941 strike by Disney animators seeking more recognition, along with economic hard times, crippled the company, but World War II (1939–1945) reenergized the Disney Company through government commissions. The Three Caballeros (1944) was made at the behest of Nelson Rockefeller’s Office of the Coordinator of Inter-American
Affairs to promote “Good Neighborliness” between North America and Latin America. The conservative Disney also served as a Federal Bureau of Investigation (FBI) agent from 1940 to his death in 1966. The public image of “Uncle Walt” with a gentle smile and with roots in rural small-town America is the result of mythmaking, which masks Walt Disney's traumatic childhood and distrustful personality. Disney's vendetta against striking employees of his studio in the 1940s betrays not only a suspicious and controlling character but an anticomunist obsession. His hidden career as a secret informant in the last two decades of his life gives a perverse twist to the family entertainment Disney has come to symbolize.

The Disney television show went on the air in 1954. Theme parks proved to be far more successful than animations and live-action films and television. Disneyland in Anaheim, California, opened in 1955, followed by Disney World in Orlando, Florida, in 1971. Tokyo saw the Japanese version of Disneyland in 1983, France in 1992, and Hong Kong in 2005. Having languished after Walt Disney's death, the Disney Company resurfaced under Michael Eisner in the 1980s. Disney has now grown into a global business conglomerate of film studio, television network, cable company, magazine, merchandise bearing various Disney logos, theme parks and resorts, and other ventures, with revenues totaling over $25 billion around the turn of the century. Disney also works through the Touchstone label, Miramax Films, Buena Vista International, and other business entities to produce and distribute less family-oriented shows.

With its increasing monopoly of media and entertainment, Disney has given rise to the phenomenon of Disneyfication, that is, trivialization and sanitization. The key to the success of the “Magic Kingdom” is indeed carefully controlled, heavily edited images of childhood innocence and fun. Yet what appears to the child to be happy tunes and carefree joy often veils sexist, racist, ageist, and neo-imperialist reality. From Sleeping Beauty to the Little Mermaid to Mulan, every Disney female lead embodies childlike simplicity and pleasure further leads to an acquiescence to Disney's ahistorical and apolitical universe. Assuredly, growing up anywhere in the world, one is invariably nurtured on Disney's breast milk of superior quality in terms of ingenuity and craftsmanship. To contend that consumers have been fed with something aesthetically refined but culturally suspect is likely to provoke vigorous opposition. Yet the 1995 defeat of the proposed 3,000-acre Disney theme park in Virginia's Civil War battlegrounds signals the potential of grassroots resistance to corporate greed and expansionism. With the shadows of the omnivorous, lawsuit-happy Disney Company looming over the twenty-first century, new battles will be fought far away from Virginia. Globalization has brought Disney to every corner of the world. In the company of giants such as McDonald’s, Nike, Coca-Cola, and Microsoft, Disney's transnational operations will continue to perpetuate Americanization globally, but it remains a severely constricted vision of America, one enjoyed principally by middle-class visitors to Disney World and passive consumers of Disney culture.

DISSIDENTS
Dissidents are people who work to alter the established social, political, economic, or cultural system. Because they threaten the established order, dissidents are often subjected to official repression and punishment. Still, dissidents have been major contributors to social, political, economic, and cultural change.

Although dissidents have varied foci, the term most commonly refers to political dissidents. Political dissidents do not simply oppose a particular political leader or group of leaders; rather, political dissidents seek to change the existing political system. Political dissidents have been most prominent in authoritarian polities. In particular, the term has been applied to public opponents of communist rule. In this context, the earliest clear official use of the term was in the 1965 trial of writers Andrei Sinyavsky (1925–1997) and Yuri Daniel (1925–1988) in the former Soviet Union; in this case, the ruling authorities used the English word dissident to suggest that the defendants were under foreign influence (and therefore treasonous).

Political dissidents in communist polities have employed primarily nonviolent methods of dissent. Most commonly, dissidents in communist polities have used pseudonyms to write critical political tracts that circulate underground domestically and are smuggled abroad to be published for a wider readership. Noted examples include Andrei Sakharov (1921–1989) and Alexander Solzhenitsyn (in the former Soviet Union), Václav Havel (in Czechoslovakia, now the Czech Republic), and Wei Jingsheng (in China). Dissidents in communist polities also have formed informal discussion groups and formal dissident organizations. For instance, from 1980 to 1981 labor activist Lech Walesa led Poland’s dissident Solidarity Free Trade Union, and in 1998 Chinese dissidents Wang Youcai and Xu Wenli founded a domestic opposition political party, the China Democracy Party. In addition, dissidents in communist polities have engaged in public protest actions, such as hunger strikes and street marches. Some of the most well-known protests occurred in 1989; in Eastern Europe that year, massive public demonstrations, such as those in the former Czechoslovakia, ultimately led to the fall of communism, while in China, widespread popular demonstrations were crushed ruthlessly.

Political dissidents have been prominent in noncommunist authoritarian polities as well, especially in Central and South America, Africa, and Southeast Asia. These dissidents employ many of the same nonviolent forms of dissent found in communist polities. Noted individuals of this sort include Aung San Suu Kyi of Myanmar (formerly Burma) and Francis Seow of Singapore. In addition, dissidents in noncommunist authoritarian polities sometimes have led military struggles seeking to overturn the ruling order. Because dissidents typically lack military resources comparable to those of the ruling authorities, dissident groups that use violent means to pursue their goals commonly employ guerilla tactics. A prominent example is the South African guerilla insurgency against the apartheid system from the 1940s to early 1990s. Another notable case is the Sendero Luminoso (Shining Path) Maoist guerilla movement in Peru, which was most active from the 1960s to 1980s.

In democracies, criticism of leading politicians and policies is commonplace, but opposition to the democratic system is more rare. Still, even in democratic polities, critics of politicians and policies at times have been labeled dissidents and punished for treason against the established order. The most noted instances have occurred in the United States against individuals and groups who publicly opposed existing policies toward the working class and racial minorities. For example, in 1919 and 1920 roughly ten thousand members of labor organizations and socialist-communist groups were arrested in the Palmer Raids, directed by Alexander Mitchell Palmer (1872–1936), the U.S. attorney general. Similarly, in the late 1940s to mid-1950s, hundreds of left-leaning individuals were investigated or blacklisted from certain types of employment. Further, during the civil rights movement of the 1950s and 1960s, many prominent opponents of race-based segregation and political exclusion were arrested and physically harmed by ruling authorities.

Because dissidents challenge established authorities, they often receive harsh treatment. The most common form of official repression is imprisonment, often for extremely lengthy periods. South African antiapartheid leader Nelson Mandela, for example, was jailed for twenty-seven years. Still, many imprisoned dissidents continue to write critical tracts even while behind bars; further, many succeed in smuggling out their texts, or preserve them for later publication. Other typical forms of punishment include blacklisting from employment opportunities, placement under house arrest, continual official surveillance, tax investigations, and forced exile. On occasion, ruling authorities also tacitly encourage paramilitary groups to physically harm or even kill dissidents.

Given these risks, few dare to engage in dissent. Those who do often exhibit an unusual psychological profile, characterized by an unrelenting commitment to ideals and a profound stoicism toward the loss of personal secu-
rity. At the same time, many turn to dissent only after experiencing what they feel are undeserved limitations on their own social, economic, or political status.

Indeed, despite the harsh punishment meted out to most dissidents, some ultimately succeed in transforming the established order, and even rise to prominent positions in the newly established system. For example, oft-harassed American civil rights activist Thurgood Marshall (1908–1993) later served on the U.S. Supreme Court. Similarly, once-imprisoned political dissidents Lech Walesa, Václav Havel, and Nelson Mandela were elected to their nation’s highest political office after democratic political rule was achieved.

DISTINCTIONS, SOCIAL AND CULTURAL
Over the past forty years, there has been a surge of academic inquiry into the relationship between cultural practices and social stratification. In particular, scholars have explored how distinctions drawn between members of varying social strata with respect to lifestyle, preferences, habits, and consumption practices contribute to unequal access to economic and social rewards. This article reviews key works addressing the role of cultural demarcations in the persistence of class inequality, highlights major debates within the field, and suggests potentially fruitful directions for future research.

DISTINCTIONS AND CLASS CLOSURE
Through his concept of social closure, classical social theorist Max Weber (1958) described how social distinctions play a crucial role in the production of systems of power. According to Weber, advantaged groups within societies establish and retain social dominance through monopolizing, or “closing,” access to valued resources and opportunities at the expense of other members of the community.

In order to facilitate such exclusion, privileged groups tend to adopt one or more “badges” of social standing so that group membership is readily perceptible, and the distribution of resources can be restricted within group lines.

Building upon Weber’s work, Thorstein Veblen and Norbert Elias explored techniques used specifically by economic classes to distinguish themselves from the less affluent masses. In Theory of the Leisure Class (1899), Veblen described how the wealthy use material boundaries—specifically, the conspicuous consumption of costly consumer goods and services—to outwardly demonstrate their superior standing. Conversely, Elias’s The Civilizing Process (1978) documents the development of elaborate behavioral codes and etiquette rituals established by elites in premodern Europe to signal membership in the more cultivated classes.

CULTURE AS CAPITAL: THE WORK OF PIERRE BOURDIEU
However, it is the work of French theorist Pierre Bourdieu that has been the most influential in shaping contemporary sociological understandings of the relationship between cultural practices and social stratification. Expanding upon Weber’s, Veblen’s, and Elias’s earlier insights, Bourdieu argues in Distinction (1984) that cultural boundaries play a vital role in the reproduction of class inequalities.

According to Bourdieu, differences in material conditions result in different modes of interpreting and experiencing the social world. In particular, the institutions of family and schooling transmit class-specific values to younger generations. As a result of their upbringing, individuals develop goals, attitudes, knowledge, preferences, tastes, codes of appropriate conduct, and consumption practices consistent with their class position, the constellation of which Bourdieu refers to as cultural capital. Due to their restricted standard of living, for example, the lower classes develop cultural preferences and practices consistent with their subsistence and survival needs; members of these classes emphasize functionality and usefulness over more ethereal qualities such as aesthetic or intellectual value. Upper-class values, on the other hand, are characterized by their distance from necessity, or their removal from the immediate concerns of present-day life. In contrast to the “base” or “vulgar” tastes of the working classes, they emphasize complexity and form over use-value. An important component of upper-class cultural capital is that it is difficult to acquire and exclusive in nature; because the pursuit of these cultural practices and forms of understanding tend to require dedication of significant economic, mental, educational, and/or temporal resources, they are a luxury available only to those who have risen to a certain level of economic comfort. To illus-
trate the divide between low and high cultural tastes, Bourdieu uses the example of food preferences. Specifically, he argues that lower classes gravitate toward foods that economically satisfy basic nutritional requirements, whereas higher classes cultivate more sophisticated palettes and value features such as presentation and distinctiveness of flavor. Using survey data from his native France, Bourdieu documents similar patterns in preferences for artistic genres, tastes in fashion, and participation in leisure activities.

According to Bourdieu, such seemingly benign differences in culture serve to reproduce existing class relations in two ways. First, shared norms and values foster common aspirations among members of a social class. Consequently, individuals gravitate toward class-appropriate social relations and occupations. Second, culture is used to actively exclude members of lower classes from positions of prestige. Although all social groups possess cultural resources, only the cultural capital of the dominant classes is rewarded in society at large. Key gate-keeping institutions, most notably the educational system, privilege upper-class, or “dominant” styles of thought and behavior, channeling their possessors into positions of power and economic success, while barring lower-class individuals from avenues of mobility. Through such processes of exclusion, elites consolidate their own power and pass on economic privilege to their kin. Consequently, in Bourdieu’s model, culture serves to reproduce and even mask systems of economic domination.

CRITIQUES OF BOURDIEU
Throughout the 1980s, Bourdieu’s writings, and in particular his concept of cultural capital, sparked a tremendous volume of empirical work in cultural sociology, the sociology of education, and cultural studies. Yet, after an initial surge of scholarship, researchers began in the early 1990s to highlight potential shortcomings of Bourdieu’s theory of class reproduction. Specifically, Bourdieu came under fire for (1) overemphasizing the role of early childhood experiences in determining class outcomes (Aschaffenburg and Mass 1997); (2) overestimating the importance of high culture to members of privileged strata, while underestimating the importance of moral, socioeconomic, and racial boundaries (Erickson 1996; Lamont 1992; Peterson and Kern 1996); and (3) failing to account for national and other contextual variations in the content of class boundaries (Lamont 1992). Moreover, the utility of the term cultural capital has been criticized for grouping together too many conceptually distinct variables (Lamont and Lareau 1988) as well as for its inability to reliably predict academic success (Kingston 2001). Finally, given the increasingly fragmented nature of social class and reported declines in class identification in postindustrial societies, a few more controversial scholars have questioned the very existence of class, let alone class cultures (Kingston 2000; Grusky and Weeden 2002).

SYMBOLIC BOUNDARIES: CURRENT AND FUTURE DIRECTIONS
In light of such critiques, many scholars shifted away from discussions of cultural capital and focused instead on symbolic boundaries, or conceptual distinctions made by actors to make sense of their social world. Drawing heavily on the work of classical theorists such as Émile Durkheim and more recently the work of cultural sociologist Michèle Lamont, this burgeoning literature explores the lines people draw between “us” and “them,” particularly when evaluating the worth of others (Lamont and Molnar 2002). Although current studies tend to focus on investigating the context of symbolic boundaries and how they vary by context, the field of culture and inequality could benefit from future research examining how people actively draw upon these conceptual categories of worth in their educational, occupational, and social lives, particularly in the context of microsociological interaction.

DISTORTIONS

A central precept in economics is that prices set in perfectly competitive markets provide clear signals of the value the economy places on items. In a competitive market, the value to a consumer of the last pizza sold should equal the value of the resources used in its production. An economic distortion occurs when some market intervention creates a wedge between the value of resources used in the production of that pizza and the value to consumers of consuming it. In the presence of distortions, opportunities exist to make someone better off without making anyone else worse off. This is known as a Pareto improvement.

Distortions arise for several reasons. First, companies may erect entry barriers, thereby creating market power. A monopoly is an extreme example of such market power. Firms with market power can sell goods at a price exceeding their marginal cost of production.

Second, the production or consumption of some commodity may have some positive or negative impact on other parts of the economy not transmitted through market prices. Such impacts are called externalities. A coal-fired electric utility emitting sulfur dioxide as a by-product of electricity generation creates a negative externality. In general, an unregulated economy produces too many goods with negative externalities and too few goods with positive externalities.

Third, buyers and sellers in a market may have asymmetric information about the good in question. Used-car markets are a good example. Sellers have better information about the quality of their car than do buyers. Since buyers will logically assume that owners of high-quality cars will tend to hold on to them while owners of low-quality cars will tend to sell them, a large share of the cars in the used-car market will be low-quality. Thus buyers will lower their bid for a used car. This will lead to fewer high-quality cars being sold. In the limit, this can lead to a collapse of the market, leaving both buyers and sellers worse off. This is an example of adverse selection, where the pool of items offered in a market are not representative of the typical items in existence.

Finally, government policies, intentionally or unintentionally, may create distortions. Most governments rely on income or consumption taxes to raise revenue for important government programs. Income taxes distort labor supply and savings decisions, while consumption taxes distort labor supply and consumption decisions.

Whether governments should intervene to correct distortions depends on a number of factors. Taxes on pollution set equal to the social marginal damages of pollution, for example, are generally viewed by economists as welfare enhancing. Many countries regulate monopolies or actively intervene in markets to promote competition. It may be, however, that in some cases interventions create more harm than good, in which case it may be preferable to live with the distortion. In other cases, distortions may be a necessary by-product of a desired social aim. Any redistribution through the tax system, for example, will create some degree of distortion, thereby illustrating the classic trade-off between efficiency and equity.

When facing multiple distortions, no clear prescription exists for the optimal ordering of eliminating distortions. Moreover, the first-best prescription for a given distortion may no longer hold in the presence of distortions elsewhere in the economy. This is the classic problem of the second best identified by Richard G. Lipsey and Kelvin Lancaster (1956–1957). Environmental policy provides an example of this phenomenon. In the absence of any other distortions, a first-best solution to the presence of pollution is to set a tax on pollution equal to social marginal damages. When taxes create distortions in capital and labor markets, however, this first-best prescription no longer holds. Instead, the optimal tax on pollution in most circumstances falls short of social marginal damages.

DISTRIBUTION, LOGNORMAL
The normal distribution is the single most important distribution in the social sciences. It is described by the bell-shaped curve defined by the probability density function

\[ f(X) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(\frac{-(X - \mu)^2}{2\sigma^2}\right) \]

where \( \exp \) is the exponential function, \( \mu \) the mean of the distribution, \( \sigma \) the standard deviation, and \( \sigma^2 \) the variance. As a matter of convenience, this distribution is often expressed as \( X \sim N(\mu, \sigma^2) \). If \( X \sim N(0, 1) \) so that \( \mu = 0 \) and \( \sigma^2 = 1 \), the outcome is the standard normal distribution. The resulting curve is shown in Figure 1, where the horizontal axis indicates values of \( X \) in terms of positive and negative integer values of the standard deviation. The curve's shape is typical of normally distributed variables, even when they have different means and variances.

The normal distribution has two significant features. First, the curve is perfectly symmetrical about the mean of the distribution. As a result, the distribution mean is identical to the two alternative measures of central tendency, namely, the mode (the most frequent value of \( X \)) and the median (the middle value of \( X \)). Second, the mathematical function provides the basis for specifying the number of observations that should fall within select portions of the curve. In particular, approximately 68.3 percent of the

Figure 1. The Standard Normal Distribution.
observations will likely fall within one standard deviation of the mean. In the case of the standard normal deviation, this would indicate that more than two-thirds of the observations would have a value between −1 and +1. Moreover, about 95.4 percent of the observations would fall within two standard deviations above and below the mean, and about 99.7 percent would fall within three standard deviations below and above the mean. Hence, relatively fewer observations are expected in the upper and lower tails of the distribution; the more extreme the departure from the mean the lower the score’s probability of occurrence.

**HISTORY**
The normal distribution was first associated with errors of measurement. In the latter half of the seventeenth century Galileo Galilei (1564–1642) noticed that the errors in astronomical observations were not totally random. Instead, not only did small errors outnumber large errors, but also the errors tended to be symmetrically distributed around a central value. In the first decade of the nineteenth century the mathematicians Adrien-Marie Legendre (1752–1833) and Carl Friedrich Gauss (1777–1855) worked out the precise mathematical formula, and Gauss demonstrated that this curve provided a close fit to the empirical distribution of observational errors. Gauss also derived the statistical method of least squares from the assumption that errors were normally distributed.

However, the normal distribution also appeared in other mathematical contexts. In the early eighteenth century Abraham de Moivre (1667–1754) showed that certain binomial distributions could be approximated by the same general curve. In fact, the normal curve is the limiting case for a binomial when events have a fifty-fifty chance of occurring and when the number of trials goes to infinity. A commonplace illustration is the distribution of coin tosses. In the early nineteenth century Pierre-Simon Laplace (1749–1827), when working on the central limit theorem, showed that the distribution of sample means tends to be normally distributed. The larger the number of samples, the closer is the fit to normality—a result that holds regardless of whatever the population distribution might be. Even if the scores in the population are highly skewed, the distribution of sample means will tend toward the normal curve.

Despite the fact that many mathematicians contributed to the emergence of the concept, it is Gauss whose name became most strongly linked with the discovery. As a consequence, the eponymic term Gaussian is often used instead of “normal” or “bell-shaped.”

**APPLICATIONS**
Although the normal distribution was first applied to the description of measurement errors, scientists later began to realize that it also described variation in human phenomena independent of errors of measurement. In 1835 Adolphe Quetelet (1796–1874) applied the normal distribution to many physical attributes, such as height, and in 1869 Francis Galton (1822–1911) extended the same distribution to cover individual differences in ability. The latter application is seen in those psychometric instruments in which test scores are actually defined according to the normal distribution. For instance, the IQ scores on most intelligence tests are assigned in terms of a person’s position in the distribution. Thus, under the assumption that IQ has a mean of 100 and a standard deviation of 15, a score of 130 would place the individual in the upper 2 percent of the population in intellectual ability.

Indeed, the concept of the normal distribution has become so universal that it now provides the basis of almost all parametric statistical methods. For example, multiple regression analysis and the analysis of variance both assume that the errors of prediction, or residuals, are normally distributed with a mean of zero and a uniform variance. More sophisticated methods such as canonical correlation, discriminant analysis, and multivariate analysis of variance all require a more complex assumption, namely, multivariate normality. This means that the joint distribution of the variables is normally distributed. In the special case of bivariate normality, this assumption signifies that the joint distribution will approximate the shape of a three-dimensional bell. To the extent that the normality assumption is violated, the population inferences associated with these statistical methods will become approximate rather than exact.

Given the prominent place of the normal distribution in the social sciences, it is essential to recognize that not all human attributes or behavioral events are normally distributed. For example, many phenomena display extremely skewed distributions with long upper tails. Examples include the distributions of annual income across households, the box-office performance of feature films, the output of journal articles by scientists, and the number of violent acts committed by male teenagers. Sometimes these departures from normality can be rectified using an appropriate data transformation. For instance, a lognormal distribution becomes normal after a logarithmic transformation. Yet many important variables cannot be normalized in this way. In such cases, researchers may use statistics based on the specific nonnormal distribution or else employ various nonparametric or distribution-free methods. Furthermore, it is likely that the causal processes that generate normal distributions are intrinsically different from those that generate nonnormal distributions. As an example, the former tend to emerge when multiple causal processes are additive, whereas the latter tend to appear when those processes are multiplicative.

DISTRIBUTION, POISSON

The Poisson distribution (named after Siméon Denis Poisson, 1781–1840) is used to describe certain events in time or in space. It is derived from the binomial distribution with the extension that time (or space) is thought to be continuous instead of discrete. In the case of discrete time (binomial distribution), let the probability that a certain event occurs during one period of length 1 be a constant \( p \); then the number of events \( Z \in \{0, 1, 2, \ldots \} \) happening during a certain number \( n \) of such periods is binomially distributed with parameters \( n \) and \( p \). No event influences any other event—that is, the events are mutually independent. If the length of the period is decreased to \( \Delta t \), and if we are still interested in the number of events happening during a time span of length \( n \), then this time span consists of \( n/\Delta t \) periods within each of which the event probability is \( p\Delta t \). For \( \Delta t \to 0 \) and \( np = \lambda \), the formula for the binomial distribution

\[
P(Z = k) = f_Z(k) = \binom{n}{k} p^k (1-p)^{n-k}
\]

is transformed into the formula of the Poisson distribution

\[
P(Z = k) = f_Z(k) = \exp(-\lambda) \frac{\lambda^k}{k!}.
\]

The difference between the two distributions is shown in two graphs drawn from a sample of 25,000 simulated random events:

Random variables \( X \) form a Poisson process if the following conditions hold: The probability that exactly one event occurs during a time span of length \( \Delta t \) is proportional to the length of the time span; the probability that more than one event occurs during this time span is negligible; and the number of events occurring in disjoint time intervals are mutually independent. \( X \) is the number of events that occurred from \( t = 0 \) until \( t = s \). The increments \( (X_t - X_s) \) follow the Poisson distribution.

The Poisson distribution is also called a “distribution of rare events,” because for a fixed \( \lambda \) and a large \( n \) the probability of the individual event occurring per time unit is, of course, small. An important application of the
Poisson distribution and of the Poisson process (a stochastic process whose random increments are Poisson distributed) is queuing theory; in this case, the number of new customers arriving during a fixed period is the random increment. The parameter \( \lambda \) of the Poisson distribution is called “intensity” and yields the expected value of customers arriving per time unit in this example.

Another example is the number of accidents that occur in a certain area during a given period. The distribution of this number will also follow the Poisson distribution. If one compares the number of car accidents with passengers killed with and without a seat belt, one has to compare the parameters of the two Poisson distributions and would find out whether using seat belts had a significant influence on the number of deadly accidents.

Given the conditions under which events are Poisson distributed, one could argue that customers arriving at an airport often arrive in pairs or even larger groups—which would violate the applicability of the model to real-world scenarios. Another obvious violation is due to the fact that the arrival intensities at airports (or in emergency units) are not the same over the entire day or the week, such that the model can be applied only to selected times spans during which the arrival intensities are more or less constant over a considerable period of time. Physical processes such as the decay of radioactive material are less prone to violations of this kind than processes where humans are involved; but even here—at least with the help of computer simulation—intensities that vary over time can be successfully modelled.

**DISTRIBUTION, UNIFORM**

Uniform distribution is the probability distribution in which the probability is uniform for all intervals of the same length. The definition of the continuous uniform distribution function contains two parameters, \( a \) and \( b \), which are the minimum and maximum values, respectively, that can occur in the set of numbers characterized by the distribution. The probability of any number in the interval \( (a, b) \) is \( 1/(b - a) \), and 0 outside that interval, as illustrated in Figure 1. Whether \( a \) and \( b \) are included in the interval does not matter to the integral, and in practice are sometimes included and sometimes not. The distribution is also known as rectangular distribution, because of its rectangular shape. As in all probability density functions, the area under the curve is 1. The standard uniform distribution is the special case where \( a = 0 \) and \( b = 1 \), so that the distribution takes the form of a square of height 1. In a probability distribution, the area of the curve under any interval represents the probability that a number described by the distribution occurs in that interval. For the standard uniform distribution, the probability of seeing a number in the interval \( (0, 0.5) \) would be the same as the probability of seeing a number in the interval \( (0.5, 1) \), and both would be 50 percent. In the discrete form of the uniform distribution, the probability of occurrence of all values in a finite set is equal. For example, if the set of possible values were 0 and 1, then there would be a 50 percent chance for 0 and a 50 percent chance for 1; or a 50 percent chance for getting heads and a 50 percent chance of getting tails on a fair coin.

Uniformly distributed phenomena are rare in the social world, because uniform probability implies randomness, and the social world is characterized by pattern, or the lack of randomness. However, social scientists still find use for the uniform distribution; in fact, it is the second-most used distribution after the normal distribution. The most popular use of the uniform distribution is to find the random variates of other probability distributions, such as the normal distribution. A random variate of a distribution is a number chosen randomly out of the set of numbers with likelihoods characterized by the distribution. A uniform normal variate input to an inverse cumulative probability function of any distribution will generate a random variate of that distribution. Random variates are important in Monte Carlo simulation studies, where the distribution of an outcome is estimated by taking many samples in many simulation runs. Ironically,
true random variates of any distribution cannot be com-
puted, because truly random numbers cannot be expressed
in an equation by definition. Therefore, pseudorandom
numbers are accepted, usually created by modulo arith-
metic, which have many of the statistical properties of ran-
dom numbers but repeat themselves at some point. True
random numbers are normal in the sense that, for each k,
all subsequences of the binary (or decimal, or other) expan-
sion of length k have equal probability, but pseudorandom
numbers fail on this requirement for some k.

\[ P(x) = \begin{cases} 0 & \text{for } x < a \\ \frac{1}{b-a} & \text{for } a \leq x \leq b \\ 0 & \text{for } x > b \end{cases} \]

Social scientists also use the uniform distribution to
represent lack of knowledge. For example, in a simulation
where a distribution is not known, uniform random vari-
ates are often used. Naturally, the uniform random variate
will incorrectly represent the underlying distribution.
However, the uniform distribution also represents indepen-
dence. The random variates of any distribution incor-
rectly represent dependencies on the random variates of
other modeled distributions. A random variate is only a
good model when the measure represents phenomena that
are independent of the other phenomena being repre-
sented. True independence is as rare as true randomness in
the social world. A simple illustration of the problem with
using the uniform distribution to represent the lack of
knowledge is Bertrand’s paradox. In Bertrand’s paradox, a
cube is hidden in a box with a side that has an unknown
length, say between 3 and 5 centimeters. Using modulo
arithmetic can then generate random numbers between 3
and 5 centimeters, and take their average in multiple runs
of 4 centimeters to estimate the side length. Random
numbers could also be generated for all the possible sur-
faced areas, between 54 and 150 square centimeters, and all
the possible volumes, between 27 and 125 cubic centime-
ters. However, if those possible measures are averaged as
well, then an impossible cube emerges with a length of 4
centimeters, a surface area of 102 square centimeters, and
a volume of 76 cubic centimeters.

DIVERSITY

Diversity, one of the buzzwords of the early twenty-first
century, has become a concept that has multiple meanings
to different groups of people. Although dictionaries usu-
ally define diversity by using terms like “variety,” “dif-
ference,” or “dissimilarity,” social scientists usually talk about
diversity in at least four different ways.

1. **Counting diversity** refers to empirically enumerat-
ing differences within a given population. Using this def-
nition, social scientists take a particular population and
simply count the members according to specific criteria,
often including race, gender, and ethnicity. In addition, it
is possible to take a particular unit within a society like a
school, workplace, or government and compare its race,
ethnic, or gender distribution to that of the general pop-
ulation. Often, suspicious questions are raised the farther
the diversity of a subunit differs from that of the larger
population.

2. **Culture diversity** refers to the importance of under-
standing and appreciating the cultural differences between
race, ethnic, and gender groups. Since members of one
culture often view others in relationship to their own stan-
dards, social scientists using the culture diversity defini-
tion would argue that it is important to show that
differences do not have to be evaluated along a good-bad
or moral-immoral scale. With greater tolerance and
understanding, the argument goes, different cultural
groups can coexist with one another in the same society.

3. **Good-for-business diversity** refers to the belief that
businesses will be more profitable and government agen-
cies and not-for-profit corporations will be more efficient
with diverse labor forces. According to this approach,
members of particular cultural groups are more effective
than non-group members in dealing with their own
groups so it is in the interests of organizations to diversify
workers and managers.

4. **Conflict diversity** refers to understanding how dif-
derent groups exist in a hierarchy of inequality in terms of
power, privilege, and wealth. According to this definition,
dominant groups oppress subordinate groups in many societies and it is important for social scientists to understand the nature of this oppression in order to help attain a more egalitarian society.

In the real world, these four approaches often overlap. However, people using different approaches often ask different types of questions. One can see how this works by examining a hypothetical city in the United States that is having difficulty between the local police department and the black and Hispanic population.

A social scientist with a counting diversity perspective might compare the black and Hispanic distribution in the police department with the distribution in the city. Typically, blacks and Hispanics would be underrepresented in the police department and even more highly underrepresented at the upper levels of the department.

A culture diversity scholar, on the other hand, would be more concerned with how the police understand the black and Hispanic communities since this also affects their actions. Do the predominantly white police interpret certain types of speech and clothing as threatening when it is simply part of the black and Hispanic subculture? Do they act in ways that inadvertently disrespect members of the community, thus causing even more tension? Being more sensitive to black and Hispanic cultural values might make the job of the police easier.

The good-for-business perspective would argue that the police would be more effective if they had more black and Hispanic officers who would be more likely to be familiar with the culture of those communities. In addition, members of the community might not be so hostile if the police were seen as some of their own.

Finally, culture conflict social scientists would argue that the police represent the interests of the dominant group: wealthy, white men in business and politics. The police represent the property rights of the dominant group and enforce the laws that they have enacted. Black and Hispanic police officers enforce the same unfair laws as their white colleagues, although they may do it more humanely. The goal is not just to have a more representative and culturally sensitive police force. The goal is to change the laws in order to have a more equitable society.

Concerns about diversity, however it is defined, also intersect with policies like affirmative action. Employment-based affirmative action is based on comparing the racial distribution of employees in a given workplace with the racial distribution of the pool of workers who are qualified for a specific job. This is counting diversity. In the United States, employers with $50,000 in federal contracts and fifty or more employees are required to make a “good faith effort” to achieve a representative labor force; that is, they must try. Formal hiring quotas, where employers are legally obligated to hire a certain percentage of underrepresented workers, are more difficult to justify. In India, on the other hand, these hiring quotas are used much more extensively.

In higher education, both counting diversity and a version of culture diversity are involved. According to the 2003 Grutter and Gratz decisions of the U.S. Supreme Court, affirmative action in college admissions is constitutional because it is in the educational interests of all students to be exposed to a diversity of views on campus. Racial diversity is one way to enhance the diversity of views. However, strict numerical comparisons and formulas cannot be used. Instead, “holistic” assessments of each candidate must take place in order to achieve an undefined “critical mass” of each student group. Since white and Asian students are overrepresented in American higher education, these critical mass guidelines refer mainly to underrepresented minorities like blacks, Hispanics, and Native Americans. A good-for-business perspective is also involved since the court noted that law schools and, to a lesser extent, all of higher education train future leaders who should be selected from all racial groups.

Neither affirmative action in employment nor in higher education reflects the conflict diversity perspective since the role and structure of higher education and the economy is not questioned. The relative power of workers and their bosses/managers is not addressed. The purpose of higher education is not addressed. All that is addressed is the racial characteristics of those who occupy various positions. When reading an article about diversity, it is critical to understand which approach the author is using.

**DIVESTITURE**

Countries that employ economic sanctions have a number of economic instruments with which they may induce compliance by their targets. Among these is disinvestment...
or divestiture, in which they shed their capital holdings within the target state. When sanctioning states divest, they effectively seek to reverse the benefits of foreign direct investment (FDI) flows into the target state. Whereas FDI increases states' productive capital stock by funding factories and infrastructure, disinvestment seeks a liquidation of this capital stock. Although divestiture has rarely been used (because, to be effective, the sanctioning state must have previously invested heavily in the target country), when the conditions favor this policy tool, it can be particularly effective.

Perhaps ironically, the short-term effects of divestiture may actually benefit the target country. Because factories and infrastructure are typically immobile, they must be sold in-place, generally to entrepreneurs within the target state and often at fire-sale prices. Thus, in the short term divestiture does little to reduce target states' capital stock; it simply transfers ownership of immobile capital assets from foreign to target state stakeholders.

While the short-term effects of disinvestment may be negative, its long-term effects can prove especially damaging to the target country. This is not only because disinvestment chills future FDI inflows but also because foreign management and technology are mobile and these are generally withdrawn after divestiture. Without access to foreign technology, spare parts, and management skills, in the long run the divested capital stock will eventually run down and become far less productive, becoming a drain on target-state entrepreneurs and increasing their calls for an end to the policies deemed offensive by the divesting state(s).

A notable past case of divestment was undertaken against apartheid South Africa under the context of the Reverend Leon Sullivan's voluntary code of conduct that pressured (mostly U.S.) businesses to liquidate their South African holdings during the 1980s. In the short term South African entrepreneurs were able to acquire a set of highly productive assets at low prices and the black employees of these enterprises often suffered under their new management (Barber 1982). In the long term, however, the lack of foreign capital, technology, and management expertise began to tell on the divested industries, increasing South African entrepreneurs' calls for an end to apartheid. Their pressure was one of the keys to the eventual demise of apartheid (Major and McGann 2005).

More recently, a number of universities and religious organizations, such as the Presbyterian Church (USA), have called for a similar disinvestment campaign against Israel for its continued occupation of Gaza and the West Bank. If U.S. companies could be pressured into divesting, it could prove damaging to the Israeli economy: in 2003, the United States' FDI position in Israel equaled 5.62 percent of Israeli gross domestic product. Although Israeli entrepreneurs could be expected to reap a bonanza in the short term, should disinvestment proceed, cutting this crucial link between Israel and U.S. technology, managerial skills, and best practices, it could seriously hobble the Israeli economy in the long run.

In cases in which a sanctioning state has substantial FDI holdings in the target state, and where it is patient enough to ride out the negative, short-term effects of disinvestment, divestiture can be an effective nonviolent policy tool to persuade another nation against engaging in unsavory activities.

DIVINE RIGHT
The belief that a community's earthly protector has a unique, authority-conferring relationship with the divine has existed in virtually all forms of one-person rule throughout human history. The concept of the "divine right of kings" was developed as a formal theory of legitimacy in the period following the Middle Ages in Europe. It states that God directly authorized the rule of a Christian monarch for life by creating him (or her) as the hereditary heir to the throne. This not only sanctifies and clarifies the often disruptive process of succession, but also puts the monarch beyond human accountability and enjoins all believers to obey unhesitatingly, thereby ending the recurring instability in Europe caused by divided loyalties between the people's political and spiritual leaders. It was initially propounded against rival claims of authority by feudal lords as much as the pope, thereby serving to strengthen the burgeoning nationalism of the fifteenth and sixteenth centuries. In the seventeenth century, the French bishop Jacques-Bénigne Bossuet (and various English theorists before him) argued for divine right in the face of emerging theories of legitimacy based on the consent of the ruled. In the midst of the reign of Louis...

XIV (the “Sun King”), France’s greatest exemplar and proponent of divine right, the Glorious Revolution of 1688 put the doctrine largely to rest in England, where it was replaced with a democratically based, limited constitutionalism that revolutionized the practice and acceptance of authority.

 Whereas the implied infallibility of God’s deputy in the European model tended to have distinctly absolutist implications, the conditionality in the Chinese conception of a “Mandate of Heaven” served to preserve as well as destroy dynasties of various lengths after it was first formulated during the Zhou dynasty (1050–256 BCE). This Chinese variation of divine right is based on the idea that heaven protects human welfare by establishing rulers whose mandate is to be wise and just. If they fail in this, the mandate is passed on as evidenced by their physical overthrow. Originally an outgrowth of pagan ethics and cosmology, it was blended with Confucian principles and Buddhism in such a way as to emphasize the virtues of moderation and reserve on the Emperor’s part, rather than power and splendor. By the late sixth century, Buddhism, Confucianism, and other key elements of Chinese culture began to take hold in Japan. A century later, using terms such as “Mandate of Heaven,” Emperor Temmu and his consort and successor Jitô established the image of the emperor (Tenno) as a descendant of the sun goddess Amaterasu and ruler of “all under heaven.” Since then, the Tenno has been seen as a bridge between heaven and earth, with duties to Heaven as well as to the people. This distinction was soon added that of “Servant of the Buddha,” and the Tenno served in this leading religious role until the end of the nineteenth century. For much of Japanese history, the Tenno has served as the religious and cultural leader, lending official sanction to the policies and authority of a largely independent and better-armed political ruler. Throughout history, the prevalence of tenets comparable to divine right around the world suggests that the belief that worldly authority and divine providence coincide is more than simply a convenient premise for establishing authority, but instead speaks to a fundamental human longing.

DIVISIA MONETARY INDEX

Aggregation theory and index-number theory have been used to generate official governmental data since the 1920s. One exception still exists. The monetary quantity aggregates and interest rate aggregates supplied by many central banks are not based on index-number or aggregation theory, but rather are the simple unweighted sums of the component quantities and averages of interest rates. The predictable consequence has been induced instability of money demand and supply functions, and a series of “puzzles” in the resulting applied literature. Without coherence between data aggregation formulas and the models within which aggregates are embedded, stable structure can appear to be unstable. This phenomenon has been called the Barnett critique by Alec Chrystal and Ronald MacDonald (1994). In contrast, the Divisia monetary aggregates, originated by William A. Barnett (1980), are derived directly from economic index-number theory and are now available from some central banks.

Statistical index-number theory provides indexes that are computable directly from quantity and price data, without estimation of unknown parameters. For decades, the link between statistical index number theory and microeconomic aggregation theory was weaker for aggregating over monetary assets than for aggregating over other goods and asset quantities. Once monetary assets began yielding interest, monetary assets became imperfect substitutes for each other, and the “price” of monetary-asset services was no longer clearly defined. That problem was solved by Barnett, who derived the formula for the user cost of demanded monetary services. Barnett’s results on that user cost set the stage for introducing index number theory into monetary economics.

Let \( m_t = (m_1 t, m_2 t, \ldots, m_m t)’ \) be the vector of real balances of monetary assets during period \( t \), let \( r_t = (r_1 t, r_2 t, \ldots, r_m t)’ \) be the vector of nominal holding-period yields for monetary assets during period \( t \), and let \( R_t \) be the yield on the benchmark asset during period \( t \). The benchmark asset is defined to be a pure investment that provides no services other than its yield, so that the asset is held solely to accumulate wealth. Let \( \pi_t = (\pi_1 t, \pi_2 t, \ldots, \pi_m t)’ \) be the vector of monetary-asset real user costs, with \( \pi_i t = \frac{R_t - r_i}{I_t + R_t} \).

The user cost formula measures the foregone interest, which is the opportunity cost, of holding a unit of monetary asset \( i \).

In economic aggregation theory, there exists an exact aggregator function over quantities. Let that aggregator function over monetary assets be \( n \), so that the exact monetary aggregate, \( M_n = n(m_t) \). Statistical index-number theory enables us to track \( M \) exactly, without estimating the unknown function, \( u \).
In continuous time, the exact monetary aggregate, $M_t = u(m^*_t)$, can be tracked exactly by the Divisia index, which solves the differential equation
\[
\frac{d \log M_t}{dt} = \sum_i s_{it} \frac{d \log m^*_i}{dt},
\]
where $s_{it} = \frac{\pi_{it}m^*_{it}}{y_t}$ is the $i$th asset's share in expenditure on the total portfolio's service flow. The dual user cost price aggregate, $\Pi_t = \Pi(\pi^*_t)$, can be tracked exactly by the Divisia price index, which solves the differential equation
\[
\frac{d \log \Pi_t}{dt} = \sum_i s_{it} \frac{d \log \pi_{it}}{dt}.
\]

In continuous time, the Divisia index, under conventional neoclassical assumptions, is exact. In discrete time, the Törnqvist approximation is:
\[
\log \frac{M_t}{M_{t-1}} = \sum_i \pi_{it} \left( \log m^*_t - \log m^*_{t-1} \right),
\]
where $\pi_{it} = \frac{s_{it}}{2} (s_{it} + s_{it-1})$.

The user cost aggregate, $\Pi^*_t$, then can be computed directly from Fisher's factor reversal formula, $\Pi^*_t M_t = \prod_i m^*_t$.

The formula for Divisia monetary aggregation has been extended to risk aversion and to multilateral (international) aggregation within a common currency area, with particular reference to the concerns of the European Central Bank. Many of those extensions have been collected together in Barnett and Apostolos Serletis (2000).

### DIVISION OF LABOR

The phrase *division of labor* can justifiably be used to indicate any form of work specialization, such as the division of labor between men and women; and yet, ever since Adam Smith's *The Wealth of Nations* (1776), it has come to refer to the division of tasks within an industrial process. Smith saw the division of labor within the industrial process as enormously efficient and illustrated his argument by the now hallowed example of the pin factory. A competent pinmaker, we are told, could not make more than twenty pins a day, whereas, upon dividing the tasks into eighteen operations, such as drawing, cutting, grinding, and so on, ten men can make over 48,000 pins in a day. On an average, therefore, each individual's productivity is increased 240-fold. The example is especially interesting because the productivity increase involves no change in technique—it is purely a case of applying existing knowledge more efficiently. The only limit to such productivity lies in the ability to sell the additional output, hence Smith also tells us “That the division of labour is limited by the extent of the market” (1776).

We are emphatically told in chapter 1, Book I, of the *Wealth of Nations* that the division of labor is the most important reason for greater production and is the primary force leading to prosperity:

> The greatest improvement in the productive powers of labour, and the greater part of the skill, dexterity and judgement with which it is anywhere directed, or applied, seems to have been the effects of the division of labour. (p. 13)

> It is the great multiplication of the production of all the different arts, in consequence of the division of labour, which occasions, in a well-governed society, that universal opulence which extends itself to the lowest ranks of the people. (p. 22)

Three reasons are given why a concentration of effort upon a single task increases efficiency. First, the skill of individual workers is much improved by specialization; secondly, workers save time and effort involved in having to switch from one operation to another; and finally, the division of labor facilitates the invention of machinery. The three reasons are most applicable only in manufacturing and Smith notes that agriculture is not suited to the division of labor, with the implication that one is not to expect much growth in that sector.

The rhetorical force of Adam Smith's presentation has to be separated from its economic analysis. All individuals have identical capacities in Smith's presentation and he ignored the traditional view of the division of labor as permitting individuals to perform those tasks that were most suitable to them. Dugald Stewart, Smith's successor at Edinburgh, criticized each of Smith's three reasons. Stewart grants that a workman gains in dexterity by concentrating on one task, but the efficiency gains thus obtained he considers to be quite limited (Stewart 1855, vol. 8, p. 315). Secondly, while it was perfectly true that a worker saves time by not having to change jobs, such gains are of small magnitude. If, then, the division of labor is to explain the productivity of labor, it must be by its influence upon the invention of machinery (p. 319).
Stewart now made two very significant innovations. First, his analysis of production focused on breaking production processes down into a series of simple tasks, as simple tasks are the ones that are most easily mechanically duplicated; gains in time and dexterity followed as a corollary of this attempt at simplification. Secondly, the entrepreneur and the worker is put at the center of the stage. Stewart doubted that workers themselves would engage in the invention of labor-saving machinery, as Smith had conjectured they would, because the effect of such improvements indeed might even lead to his being unemployed. It is the capitalist who is driven by the lure of profits to continually improve his machinery. E. G. Wakefield later elaborated upon this far-reaching criticism by insisting that every successful division of labor must be accompanied by a plan for its subsequent combination. Coordination was prior to, and critical for, the successful division of labor. Smith’s one-sided emphasis Wakefield found to be “not only very deficient but also full of error” (Smith [1776] 1840, p. 33).

Later generations have made the division of labor the paramount principle underlying profitable international trade. The international division of labor is a feature that Smith himself laid little stress upon and the argument about its centrality is based on a misinterpretation. The phrase division of labor can be used for any activity where there is some element of specialization. When used in the context of international trade, to suggest that trade between two countries is beneficial in allowing two countries to specialize, what is being referred to is, however, not at all the same phenomenon that occurs in the pin factory. The gains here typically arise from the different endowments of the two countries, not from the subdivision of tasks within a unified process.

From the scholarly point of view it must be regretted that Smith (1) neglected the fairly extensive British tradition—Petty, Maxwell, and Harris, to name a few—of viewing the division of labor as a factor in productivity, and (2) failed to acknowledge his debt to the Encyclopédie (see Kindleberger 1976, p. 1). Not only does the example of pinmaking appear to have been taken from the French Encyclopédie, the three advantages of the division of labor are also distinctly stated there as well. (This point is distinctly noted by Edwin Cannan, editor of the fifth edition of the Wealth of Nations, and subsequently by Roy Campbell and Andrew Skinner, editors of the 1976 edition.) When Adam Smith and Adam Ferguson fell out in the 1760s and 1770s, Smith appears to have accused Ferguson of plagiarism—to which charge Ferguson justifiably replied that he had only dipped into the same French source as Smith (Hamowy 1968).

Charles Babbage (1791–1871) and, independently, the Italian economist Melchiorre Gioja (1767–1829) elaborated on Stewart’s insight that work could be matched to individual abilities: “The master manufacturer, by dividing the work to be performed into different processes each requiring different degrees of skill and force, can purchase exactly that precise quantity necessary for each process” (Babbage 1832, pp. 137–138). (Babbage also claims that needlemaking is more illustrative of the division of labor than pinmaking.) Andrew Ure considered the same issue through the employer’s eyes and noted how important subdivision is to the social control of industry. The function of science is to mechanize every “difficult” process so as to reduce the bargaining power of skilled workers (Ure 1835, p. 19). Wherever a process requires particular dexterity and steadiness of hand, it should be withdrawn as soon as possible from the “cunning” workman, who is prone to many kinds of irregularities, and entrusted to a specific mechanism, so self-regulating that a child could supervise it. Babbage, Gioja, and Ure foreshadow the twentieth century views of F. W. Taylor and Henry Ford, who wanted to replace worker initiative with rules and assembly lines. With Ford and Taylor, and their associated production philosophies Tayloration and Fordism, the view of the worker as robot was virtually complete. It appeared that efficiency requires a dehumanized work environment. Yet labor disputes and poor production quality, quite apparent to all by the 1980s, suggest to many that traditional Tayloration and Fordism are at an end. The latest step has been to globalize the division of labor by shipping out unskilled work to low-wage countries, a process that has the added advantage of removing the alienated worker from view.

Ensoenced within the Wealth of Nations, however, was a potent message about alienation. After having extolled the division of labor in Book I, in Book V Smith emphasized the way in which the division of labor turned human beings into mechanical morons: “The man whose whole life is spent in performing a few simple operations … has no occasion to exert his understanding, or to exercise his invention…. He naturally loses, therefore, the habit of such exertion, and generally becomes as stupid and ignorant as it is possible for a human creature to become” (p. 781). This acquired stupidity makes the ordinary worker an indifferent family man and a poor citizen. Because of this considerable danger to civil society, Smith went against his usual principles and urged the state to become involved in providing primary education. The suggestion that primary education would suffice to save the worker from an alienated, almost disembodied, existence drew Karl Marx’s acid remark that Smith had sought to cure the major ill of industrialism with a “homeopathic dose.” It is rumored that Smith was indebted to Rousseau for the “alienating insight,” but, be that as it may, Smith is properly considered parent of the major stem of modern labor relations and stepfather to the opposition. The
dominance of Taylorism as the ideology of work in the 1930s caused a reaction that is exemplified by Elton Mayo’s insistence that human relations in the workplace are crucial to maintaining productivity.

The casual treatment of the worker’s welfare in the American workplace is to be contrasted with the considerable care taken in the molding of engineers. William Wickenden wrote that educational leaders of the 1920s saw the college as being like a factory and urged that colleges must take raw material and “turn out a product which is saleable,” with the significant implication that “the type of curriculum is in the last analysis not set by the college but by the employer of the college graduate” (as quoted in Noble 1984, p. 46). The most effective spokesman for engineering education, William Wickenden emphasized teamwork, rather than individualism. The new “engineer for industry” was urged to be a good subordinate. One notes that these are the very complex of attitudes that America had to “relearn” from Japan in the 1970s and 1980s!

The social approach to technology looks at Fordism as the primary source of misleading insights. In turn, Fordism arose from glorifying the productivity of the pin factory. In order for large capital expenditures to take place, both corporation and state need to be socially stable. Yet such social stability is difficult to arrange under modern conditions, unless one pays attention to the worker’s welfare. The full message of the division of labor is a complex one and far too much has been lost by focusing upon the making of pins.

In addition, the effect of the division of labor was to fix attention on one simple operation, whereas the improvement of machinery required knowledge of a great variety of operations. The “popular” view of technological progress sees it as occurring outside the control or guidance of the worker, who has the challenge of adjusting himself to the technology at hand. And yet, one has to remember that perhaps as much as 40 percent of the technological improvements that occurred in the textile industry during the Industrial Revolution have no assigned source. These were all improvements that occurred as workers made small, “invisible” improvements whose aggregate effect was quite noticeable. Of course, there are no rules for obtaining such invisible changes, but we can be sure they will happen if we possess a literate, inquisitive, and enterprising labor force. The creation and sustenance of such a labor force is a social process and it makes the successful implementation of any technology policy the result of investment in building up the requisite social foundations. The modern history of labor use has scarcely proceeded along these lines, however (see Rashid 1997 for a historical review).

The appropriateness of the Fordist model has also been called into question by new alternatives to mass production, such as the Just In Time (JIT) production (also called “flexible specialization”) adopted in Japan. The smallness of readily available markets in Japan meant that firms needed to adapt their production strategies. Instead of mass-producing at low costs, they now had to produce relatively small quantities of high quality goods at affordable prices. This was a considerable challenge, requiring product innovation as well as cost minimization.

JIT manufacturing also required further changes in the philosophy of production, best exemplified by the automobile industry. Automobiles are discrete products—as opposed to dimensional products, which are sold by volume or weight. Resetting machinery for discrete products takes time; to reduce the costs associated with machine resetting, workers needed to have several skills. Because quality control became essential to every step of the production process, and because even research and development needed to be discussed factory-wide, unskilled workers with minimal initiative or independence, so appropriate to Fordism, became a liability. While JIT manufacturing requires intelligent, cooperative employees, there is, of course—just as in any other system—nothing to prevent these employees from being overworked.

DIVORCE AND SEPARATION

Divorce and separation are legal actions that affect the civil marriage contract. In the United States, marriage, separation, annulment, and divorce are regulated individually by the states, although some federal benefits are available only to those who are legally married. In most cases, the person filing for the divorce or separation must be a resident for at least ninety days in the jurisdiction where the legal action is filed. Divorce is the formal dissolution of a marriage. Separation formalizes an agreement between a married couple who live apart. Some states and countries require some period of legal separation before divorce. For divorce and separation, the legal agreement may decide child custody, support, and visitation, division of assets and marital property, debt, marital home possession, and in cases of abuse, a protection order.

Separation does not end the marriage. People may choose separation over divorce for a variety of reasons, including religious or financial grounds; for the sake of the children; to retain health care, military, or tax benefits; or to live apart to assess if divorce is the best option. A separation agreement can be converted to a divorce decree.

Marriage annulment is a legal procedure declaring that the marriage never existed. The grounds for an annulment vary by state, but may apply to marriages involving underage partners (with the age varying by state), blood relatives with relationships closer than first cousins, or the absence of mental or physical capacity to consent to marriage. Other grounds for marriage annulment include intoxication, duress, refusal of intercourse, impotence, and bigamy. Most annulled marriages are brief. In the case of longer marriages the court divides the property of the parties and can determine rights and obligations related to the marital children. Children from an annulled marriage are legitimate. The history of marriage annulment dates back to Henry VIII (1491–1547), who had four of his six marriages annulled.

In the Catholic Church a member who wants to remarry after a divorce or to marry a divorced non-Catholic must have the prior marriage nullified. This is a religious rather than a legal process.

In the United States the trend since the 1960s has been toward no-fault divorces with joint legal custody of children. This contrasts with the former, adversarial process in which one person must prove a “fault” such as adultery, cruelty, desertion, habitual drunkenness, or insanity. Under no-fault laws the court must find irreconcilable differences or that the couple lived apart for a designated period of time. Critics blame no-fault divorce for the increasing divorce rate. In 1997, Louisiana was the first state to adopt “covenant marriages,” by which couples must enter into premarital counseling, and in the event that they eventually separate, undergo mandatory marital counseling, then wait two years after separation or provide proof of fault before divorcing.

In Canada the federal government sets divorce law that applies equally across provinces. No-fault divorce was adopted in 1986, allowing divorce for couples who have been separated for one year. In England marriage can be terminated by a “dissolution of marriage” or a “nullification,” the equivalent of an annulment in the United States.

In the United States only Massachusetts currently allows same-sex marriages. Canada has also recognized civil marriage between same sex partners. Many same-sex couples from other states travel to marry in Massachusetts, and the legal systems in their home states must determine how to deal with those relationships if the couples want to dissolve them, and what rights and responsibilities couples have upon dissolution, including custody and visitation rights for children born or adopted during the relationships. Similar challenges face states that grant to same-sex couples domestic partnerships, which outline the legal rights and responsibilities of those relationships but do not recognize them as marriages. In 1986 Congress adopted the Defense of Marriage Act (DOMA), which stated that no state has to recognize a marriage between persons of the same sex, even if the marriage was concluded or recognized in another state. In addition, the federal government may not recognize same-sex or polygamous marriages for any purpose, even if concluded or recognized by one of the states.
In the United States the divorce laws of the state the couple resides in, not the state they were married in, govern the dissolution; this is similar in many other countries. International divorces, in which the couple married in one country and then moved to another, face special difficulties. In addition, some countries that have religiously based governments, including Islamic and Jewish states, require religious divorces; others, including Japan and Taiwan, require only a registry office divorce, and only one spouse needs to file the paper. There are also “quickie” divorces in places such as the Dominican Republic, where there is little or no residence requirement.

DEMOGRAPHICS

Divorce rates have been rising in the United States, South Korea, and the nations of the European Union; Japan has the lowest rate. Divorce rates rose slowly from the 1860s to about 1919. There were more dramatic increases after both world wars, followed by a decrease and then a relatively stable divorce rate from 1950 to the mid-1960s. After a dramatic increase between the late 1960s through the mid-1970s, partially due to the introduction of no-fault divorces and economic prosperity, divorce rates in the United States declined, and this decline continues today. The divorce rate was 4.7 per thousand married women fifteen and older from 1990 to 1993, decreasing to 4.0 in 2001. In 2005 in the United States there were 7.5 new marriages for every 3.6 divorces per 1,000 people (Baca Zinn and Eitzen 2005).

In the United States, between 40 and 52 percent of all first marriages end in divorce, whereas in Europe the rate is one in three or four. Approximately 17 percent of married couples are separated at some time. In any given year, between 2 and 4 percent of marriages are granted legal separations. One in five marriages ends in divorce or separation in the first five years, one in three in the first ten years, and more than two-fifths within fifteen years. In the United States divorce rate is higher for remarried white women, whereas for African American women the rate is the same for once-wed or remarried women. In general, the divorce rate is lowest for white and Latino couples, and more than twice as high for African Americans.

A curvilinear relationship exists between income and divorce. Women in very low- and very high-income marriages have higher rates of divorce. Wives with higher education and husbands with higher income are less likely to divorce. Black and white couples who attend religious services together are less likely to divorce (Park 2004).

Age at first marriage is a strong predictor of marital stability. Almost 60 percent of those who marry at or before the age of eighteen dissolve their marriages within fifteen years. A factor accounting for both younger marriages and higher divorce rates is premarital pregnancy and birth. The presence of children also affects the likelihood of divorce. Childless couples divorce at a higher rate than those with children. And there is a curvilinear relationship between number of children and divorce: Divorce rates decrease as families have more children, up to four; those with more than four children are more likely to divorce than those without children. Families with children under three years old are less likely to divorce than those with children over fifteen.

Divorce is more common among those who lived together before marriage. About 40 percent of couples who lived together premaritally divorced after ten years of marriage, compared to 31 percent of those who did not live together.

Religion influences divorce. Twenty-four percent of all adults will experience a divorce over the course of their lifetime. The highest rate is for Jews (30%). Baptists have the highest rate among Christians (29%)—even those who identify themselves as “born again” have a higher than average divorce rate (27%). Protestants and Mormons have a rate of 25 percent, whereas Catholics have a rate of 21 percent (Baca Zinn and Eitzen 2005).

IMPLICATIONS OF DIVORCE AND SEPARATION FOR FAMILIES

Ex-husbands generally experience an increased standard of living after divorce. They are most often the primary wage earners in the family, and after divorce more of their income stays with them. They have more money and leisure time available to them. About 85 percent of men do not seek primary physical custody of their children, so they have greater freedom for dating, furthering their education, travel, hobbies, and sexual relationships. After divorce, males often have difficulty maintaining a routine for eating, sleeping, shopping, cooking, and cleaning. They see their children relatively rarely, and thus experience isolation. The difficulty of adjusting to divorce results in higher rates of illness and death for men.

Typically, women experience a dramatic decline in their standard of living after a divorce—to about half what their living standard had been before divorce, or about half that of divorced men. To improve their situations, divorced women often rely on several sources of wealth, including alimony, which is awarded to 15 percent of divorced women. Equitable division of marital property assumes that men and women are equal at the time of divorce, but awarding primary residences to women assumes that they are able to pay the mortgages, an assumption that disadvantages women who work in the home or those who make low wages. Two-thirds of divorced mothers are awarded child support, but in at least 60 percent of the cases fathers are late with payments.
or do not pay at all. Women may also experience isolation and over-extension due to their child care, household, and wage-earning responsibilities.

Women also may benefit from divorce. Like men, they experience an increase in freedom, albeit freedom mediated by child and household responsibilities. Domestic violence lessens, and as the divorce rate rises there is a decrease in both suicide and murder rates of women. However, women in separated couples are the group at the greatest risk of assault and murder by intimates.

At various times in history conservative social critics have argued that divorce contributes to a negative decline in the American family, and that the lack of a male role model for children of divorce has a negative effect, and can lead to crime and delinquency. But research indicates that children are resilient in coping with a divorce, and that three out of four kids become healthy and competent adults. The large majority of children in divorced families do not experience severe or long-term problems. For those children in abusive families, the quality of family life may increase.

Girls seem to fare better than boys (Seltzer 1994). Antisocial behavior on the part of children in divorced families is related to lack of parental control rather than the divorce itself. Family size, too, influences children’s well-being after divorce—the larger the family, the greater the stress on single parents, which may negatively affect children. Race also affects children’s experience of divorce. African American children are more likely to be economically disadvantaged in society and may experience more detrimental effects of divorce.

Parental contact also affects children. Parents with higher socioeconomic status are more likely to have joint legal custody of their children, and so those fathers are more likely to spend time with their children. Contact with both parents helps children adjust favorably to divorce. Children fare better when parents live in the same geographic region, which facilitates visitation.

The economic status of the family importantly predicts the problems families and children face. Children in fatherless families are more likely to drop out of school, use drugs, and engage in delinquent behavior, but the underlying cause is not divorce, but poverty (Kimmel 2004).

Economic security needs to compensate for the drop in the standard of living for divorced families. This could include policies such as a living wage for all workers to counter the low wages that divorced women find themselves confined in. There should also be a safety net providing job training and societal assistance to women and children after a divorce. This assistance could take the form of job training, public employment, quality day care assistance, adequate diet support and medical care. All would reduce the stress on children and families experiencing divorce.

DIXIECRATS

Dixiecrats (a combination of “Dixie,” referring to the Old South of the Confederacy, and “Democrats”), formally known as the States’ Rights Democratic Party, were a splinter party formed by Southern Democrats in 1948 to oppose President Harry S. Truman’s civil rights program. The term has also been used to refer to racially conservative Southern Democrats since then. With South Carolina
Governor J. Strom Thurmond leading the ticket, Dixiecrats carried four states but failed to stop Truman’s reelection. The core Dixiecrat ideologies of “states’ rights” and white supremacy have their roots in the ante-bellum South and still reverberate in the partisan alignment in the United States in the early twenty-first century.

The Democratic National Convention in 1948 approved a strong civil rights plank despite firm opposition from Southern delegates:

We again state our belief that the racial and religious minorities must have the right to live, the right to work, the right to vote, the full and equal protection of the laws, on the basis of equality with all citizens guaranteed by the Constitution....We call upon Congress to [act] in guaranteeing these basic and fundamental rights: (1) the right of full and equal political participation, (2) the right of equal opportunity in employment, (3) the right of security of person, (4) and the right of equal treatment in the service and defense of our nation. (Key 1984, p. 335)

In his fiery convention speech supporting this language, then-Minneapolis Mayor and Senate candidate (and future vice president and Democratic presidential nominee) Hubert H. Humphrey (1911–1978) did not mince words:

To those who say … that we are rushing this issue of civil rights, I say to them we are 172 years late! To those who say … that this civil-rights program is an infringement on states’ rights, I say this: the time has arrived in America for the Democratic Party to get out of the shadow of state’s rights and walk forthrightly into the bright sunshine of human rights! (History News Network 2002)

In apparent response, thirty-five delegates from Mississippi and Alabama walked out of the convention, but the walkout had actually been planned for months.

On July 17, just days after the walkout, party leaders from Mississippi, Alabama, and South Carolina met in Birmingham, Alabama. They formed the States’ Rights Democratic Party, nominated Thurmond for president and Governor Fielding Wright (1895–1956) of Mississippi for vice president, and issued a “declaration of principles” stating their opposition to “the elimination of segregation, the repeal of miscegenation statutes, the control of private employment by federal bureaucrats called for by the misnamed civil rights program” (Frederickson 2001, p. 240).

In an effort to reach out to the non-Southern Republican members of the Conservative Coalition forged in the 1930s to oppose President Franklin D. Roosevelt’s more ambitious New Deal programs, Thurmond’s campaign rhetoric focused largely on states’ rights and limited government, leading some conservatives more than fifty years later to claim that these were the true bases of the Dixiecrat movement. This view, however, is naive at best: white supremacy was the party’s raison d’être and driving force. As Thurmond thundered to the Birmingham meeting, “There’s not enough troops in the Army to force the southern people to break down segregation and admit the Negro race into our theaters, into our swimming pools, into schools and into our homes” (Frederickson 2001, p. 242). The party’s platform explicitly supported racial segregation and opposed all efforts to end it as “utterly destructive of the social, economic and political life of the Southern people.” Local appeals for votes were also perfectly clear in their intentions—an official sample ballot from the Mississippi State Democratic Party declared:

A vote for the Truman electors is a direct order to our Congressmen and Senators from Mississippi to vote for passage of Truman’s so-called civil-rights program in the next Congress. This means the vicious FEPC [Fair Employment Practices Committee]—anti-poll tax—anti-lynching and anti-segregation proposals will become the law of the land and our way of life in the South will be gone forever. (Mississippi Historical Society, undated)

In the end, the Dixiecrats carried the four states in which they were the official Democratic ticket and received one electoral vote from a “faithless” Tennessee elector. The ticket received 1,169,134 votes in total, 55 percent of which were from the four states they carried, and 99 percent of which were from Southern or border states. Even in the South, they received only 20 percent of the vote, while nationwide, they received only 2.4 percent. Thurmond and Wright received thirty-nine electoral votes, but that was not nearly sufficient to deny Truman his majority. Despite the loss, Dixiecrats remained strong enough in the Congress to block meaningful civil rights laws until the 1960s.

ORIGIN OF THE DIXIECRAT MOVEMENT

The historical roots of the Dixiecrat movement go deep into U.S. history—the Dixiecrat core ideologies of “states’ rights” and white supremacy have their roots in the ante-bellum South and the political philosophy of John Calhoun (1782–1850). The Civil War and Reconstruction cemented these philosophies in the South with the region becoming the one-party “Solid South” after Reconstruction. From 1880 through 1924, with very few exceptions, Southern and border states voted reliably Democratic for president; local and state offices were sim-
Dixiecrats

ilarly dominated by Democrats. Meanwhile, African Americans, where they could vote, were loyal Republicans, based on the same Civil War alignment. Through the 1930s, both parties kept racial issues out of electoral politics, although cases on segregation and voting rights were playing out in the courts.

The first major break in the Solid South occurred in 1928 when several southern states (excluding the four later carried by Thurmond) went for Herbert Hoover, because of the Democratic nomination of New York Governor Al Smith—a big city Northern Catholic and a “wet” to boot. In Southern Politics (1984), however, V. O. Key showed that voting patterns of “Hoovercrats” in 1928 were the precise opposite of Dixiecrats in 1948. These states all returned to the fold throughout the New Deal era.

Issues of racial justice returned to the political stage in the 1940s, beginning with A. Philip Randolph’s (1889–1979) March on Washington movement (1941), which resulted in Roosevelt’s 1941 Executive Order 8802 establishing the Fair Employment Practices Committee (FEPC) and banning employment discrimination by defense contractors. The publication of Gunnar Myrdal’s An American Dilemma in 1944 made American racism an international embarrassment and forced mainstream political and intellectual leaders to reluctantly reexamine racial issues. During the Roosevelt era, African Americans shifted to the Democratic Party as well because of Roosevelt’s progressive social policies, becoming key components of the party’s electoral coalition by the 1940s.

World War II (1939–1945) created the bitter irony of African American troops fighting and dying overseas to fight Adolf Hitler’s racist ideology only to return home to Jim Crow. (The importance of this as a grassroots catalyst of the civil rights movement of the 1950s and 1960s is often overlooked.) The irony was not lost on Truman, who in 1947 began moving toward a civil rights program. This included a strongly worded speech to the National Association for the Advancement of Colored People in June, the publication of the report of his Committee on Civil Rights in October (which recommended the steps that were later included in the 1948 Democratic Party platform), and Truman’s strong endorsement of the report in his January 1948 State of the Union speech. With fair warning, the Southern Democratic maneuvering to fight Truman and his policies thus began several months before the convention.

After Truman, with Republicans beginning to make incursions into Southern electoral politics, Democrats played down racial issues to avoid another revolt. Meanwhile, Republicans became publicly associated with civil rights, with Brown v. Board of Education (1954), President Dwight D. Eisenhower’s forced integration of Little Rock public schools (1957), and the civil rights acts of 1957 and 1960, passed despite Senate filibusters by the conservative “boll weevil” Southern Democrats. Thus, issues other than race dominated the elections of 1952, 1956, and 1960. In contrast to 1928, the Solid South provided Democratic nominee Adlai Stevenson’s only electoral votes, including all four Dixiecrat states in 1952.

With the 1964 election, the Democratic Party decisively donned the mantle of civil rights party, while the Republicans backed off. Democrats passed the stronger Civil Rights Act of 1964 (over another filibuster) and President Lyndon Johnson advocated passionately for a new voting rights act with federal enforcement; Republican candidate Barry Goldwater opposed these measures on the grounds of states’ rights and limited government. While Goldwater himself was not overtly segregationist, he was not unaware of what a states’ rights agenda meant in the South of the 1960s. Thus, it was no coincidence that in Johnson’s landslide election the only states Goldwater carried, other than his home state of Arizona, were the four Dixiecrat states plus Georgia. Thurmond (now a senator) switched parties, leading a gradual movement of Dixiecrats to the Republican Party, and bringing their issues with them.

The shift in the parties’ platforms was clearly perceived by the voters as well. The 1960 National Election Study survey showed that roughly equal percentages of Americans believed that either Democrats or Republicans were the party most likely to follow civil rights policies, with 70 percent of respondents perceiving “no difference” on school segregation and 62 percent finding no difference on policies of the FEPC. In the 1964 study, most respondents chose the Democrats as the party most likely to follow civil rights policies (50.2% on school segregation and 54.3% on employment practices), while only a small minority (6.1% on school segregation and 6.5% on employment practices) picked the Republicans.

In 1968, with Democratic Party support for civil rights now personified by nominee Humphrey, Alabama Governor George Wallace (1919–1998) attempted to revive the Dixiecrat movement through his American Independent Party. Simultaneously, Republican candidate Richard Nixon’s (1913–1994) campaign adopted a “Southern Strategy” designed to split apart once and for all the New Deal coalition that had included African Americans, urban ethnic Catholics and other blue-collar workers, and white Southerners. Both Nixon and Wallace campaigned on “law and order,” benefiting from a white backlash against recent race riots, while Wallace added the familiar focus on states’ rights and integration. Wallace carried five Southern states, including three of the Dixiecrat states, and won forty-six electoral votes—not enough to deny Nixon the election, despite the very close popular vote. Wallace’s national appeal was far stronger
than Thurmond’s; he received 13.5 percent of the vote nationally, including at least 10 percent in a number of states outside the South.

**INFLUENCE OF DIXIECRATS CONTINUES**

The Southern Strategy contributed to a period of sustained Republican success at the presidential level, with Republicans winning seven of ten elections through 2004. Nevertheless, the long-awaited Republican realignment failed to materialize; Democrats controlled the House of Representatives until 1994 and the Senate for all but six of those years, due in part to the presence in both the House and the Senate of substantial numbers of Southern Democrats. Conservative white Southern voters split their tickets between conservative Democrats at the local and state level, while voting Republican at the national level, creating a "split-level realignment." While overtly racist rhetoric was not a factor during this period, many social scientists found new forms of "symbolic racism," or "coded racism" in such issues as welfare, crime, cities, and immigration that appealed to white voters’ underlying racial resentments. Others have noted the finding that most white voters express a belief in broad principles of racial equality, but oppose specific policies designed to address them.

In the early 1990s many conservative Southern Democrats retired, while others were defeated, leading to the Republican takeover of the Congress in 1994, with Southerners holding all of the top leadership posts in both houses. Ironically, a number of white Democratic incumbents were defeated because the creation of “majority-minority” districts removed loyal Democratic African American voters from their districts.

The electoral sea change of 1994 concluded the process begun with the convention walkout forty-six years earlier—the switch of southern conservative white Democrats to the Republican Party. From the 1950s when there were essentially no Southern Republicans in Congress to the 1980s when the Democrats led slightly, to the 1990s when Southern Democrats became an endangered species—Republicans began to hold the vast majority of Southern congressional seats. It is a testament to the power of party identification as a lifetime psychological attachment that it took the death or retirement of the pre–civil rights generation—both in government and in the electorate—to accomplish this.

Along with the shift of Dixiecrats to the Republican Party, this period also saw the death of the boll weevils’ opposites, Northern liberal “gypsy moth” Republicans. While this species was never as important as its Southern counterpart, they combined to require bipartisan coalitions for all major legislation as recently as the early 1990s. Also because of a combination of retirements and electoral losses (the 2006 elections left Christopher Shays the sole Republican House member in all of the twenty-two seats of New England), the North in 2007 was even more dominated by Democrats than the South was by Republicans, with party loyalty (and party polarization) in congressional voting at historical highs in both parties. This state of affairs, with its intense ideological and regional polarizations, may be the Dixiecrats’ most enduring legacy of all.

In an odd footnote to Dixiecrat history, in December 2002, incoming Senate Majority Leader Trent Lott, a Republican from Mississippi, was forced to step down from his leadership post after making a statement at Thurmond’s 100th birthday party that seemed to endorse the Dixiecrat platform of 1948: "I want to say this about my state: When Strom Thurmond ran for president we voted for him. We’re proud of it. And if the rest of the country had followed our lead we wouldn’t have had all these problems over all these years, either” (Edsall 2002, p. A06). Following Lott’s reelection in 2006 and the Democratic takeovers, Lott was voted minority whip, making him the number-two Republican leader in the Senate.

DOBZHANSKY, THEODOSIUS
1900–1975

Theodosius Dobzhansky, born in the town of Nemirov in the Ukraine on January 25, 1900, was one of the most influential biologists of the twentieth century. He is generally regarded as the pioneer of evolutionary genetics, a field established in the 1930s that sought to integrate Darwinian selection theory with Mendelian genetics. Much of this work was summarized in Dobzhansky's magnum opus, Genetics and the Origin of Species, published in 1937. It was so influential and widely read that it is regarded as the first "textbook" of evolutionary biology in the twentieth century.

The only child of Sophia Voinarsky and Grigory Dobrzhansky, a high-school mathematics teacher, Dobzhansky early on manifested an interest in natural history and collected insects and especially butterflies in the area of Kiev. He attended the University of Kiev and graduated in 1921 with a major in biology. He subsequently accepted a position on the faculty of agriculture at the Polytechnic Institute of Kiev, where, through the influence of plant geneticist Gregory Levitsky, Dobzhansky's interests shifted from the systematics of insects like the ladybird beetle (the Coccinelidae) to the newer areas of genetics. Levitsky was part of a wider scientific movement in the Soviet Union that included such individuals as Nikolai Ivanovich Vavilov (1887–1943) and Sergei Chetverikov (1880–1959). These scientists were following efforts in American genetics to understand the mechanism of Mendelian heredity through model organisms, such as the fruit fly (Drosophila sp.). In 1924 Dobzhansky moved to Leningrad (Saint Petersburg), where he became a lecturer in genetics under the wing of Yuri Filipchenko and where he continued to study genetics by turning to basic laboratory studies of Drosophila melanogaster. At this time, he married a coworker in genetics, Natalie (or "Natasha") Sivertsev, who was to be his lifelong companion and coworker; they had one daughter, Sophie.

In 1927 Dobzhansky accepted a fellowship from the Rockefeller Foundation to study genetics with the American leader in the area, Thomas Hunt Morgan (1866–1945), and his group of fly geneticists at Columbia University, a group that included A. H. Sturtevant (1891–1970), Calvin Bridges (1889–1938), and H. J. Muller (1890–1967). While working as an assistant to Morgan, Dobzhansky learned of the latest techniques and insights into understanding the cytogenetics of the fruit fly. In 1928 Dobzhansky moved to the California Institute of Technology with Morgan and subsequently became assistant professor of genetics in 1929.

Dobzhansky's most notable breakthrough was made in 1935 when he started working with the geographically diverse Drosophila pseudoobscura. He also began to combine the laboratory methods common to the Morgan group with his interests in systematics and biogeography, which reflected his earlier Russian training. His research into the evolutionary history of this complex group of flies was aided by his novel use of the giant salivary or polytene chromosome, which permitted the reconstruction of the phylogenetic history of the model organism. This research formed the backbone of what became known as the genetics of natural populations (GNP) series, a set of studies published as papers and monographs that explored the range of species, races, and varieties of this group of flies and that sought to understand the process of speciation in genetic terms. It also informed Dobzhansky's 1937 book, his increasing independence from Morgan's fly group, and his interaction with American mathematical theorist Sewall Wright (1889–1988).

By the late 1930s Dobzhansky was recognized as one of the central figures in the "new" or "modern" synthesis of evolution that integrated Darwinian selection theory and natural history with laboratory methods and insights gleaned from Mendelian genetics. Dobzhansky increasingly drew younger workers to him, and developed an international reputation for being a "charismatic" mentor.

In 1940 he accepted a position at Columbia University, where he continued his research on Drosophila. In the 1950s his interests took a more global direction when he traveled to South America to study the speciation patterns in tropical Drosophila. In 1962 he moved yet again to Rockefeller University, where he remained until his retirement in 1970.

Dobzhansky's interests were broad and included the application of genetics to evolution and to the understanding of human beings. He wrote extensively, especially in his later years, on subjects with anthropological and philosophical themes. His synthesis of evolution and cultural anthropology appeared in 1962 under the title Mankind Evolving. In 1967 he revealed his lifelong interest in the existential aspects of evolution and in traditional religious concerns in The Biology of Ultimate Concern.

Becoming one of the most famous Soviet émigrés in the United States, Dobzhansky closely monitored the
progress of science in the Soviet Union and was especially active in campaigning against biologist Trofim Lysenko (1898–1976) and his destructive policies against Soviet genetics. Despite his feeling a strong connection to his first home, Dobzhansky was never allowed to return there.

Following his retirement, Dobzhansky moved to the University of California in Davis, where he continued to supervise an active group of geneticists. He died there on December 18, 1975, after a long battle with leukemia. Although he was closely associated with the newer evolutionary biology of the twentieth century, he remained fundamentally religious and was an active member of the Russian Orthodox Church.

DOCUMENTARY STUDIES

Documentary studies constitute an important approach in social science research. Because institutions are keen on keeping a record on their actions, documentary sources form the basis for understanding institutional behaviors. In using documentary sources, researchers are able to develop classification schemes or taxonomies to clarify societal actions and individual choices. Documentary sources are often used in conjunction with other data collection methods, such as interviews, surveys, and site observations.

Documentary studies are well suited to examine the functions and operation of how government works. In the United States the separation of powers creates a functional division of responsibilities among the three branches of government. Constitutional studies clearly rely on court decisions, judicial reviews, and lower court opinions. Students of legislative decisions can focus on congressional debate, hearings, and actions. Presidential scholars can review volumes of White House papers and archival records (such as tapes of conversations between the president and his staff).

Governmental documents enable social scientists to understand decisions made at critical stages of the policy process. Documents from governmental sources provide policy objectives, options, and the rationale behind the chosen policy options. Analysis on the content of legislative proposals from initiation through committee hearings and the final votes on the floor have yielded theoretically rich perspectives. Theodore Lowi’s (1972) comparative analysis on the content of and actions on several federal legislations led to his argument that the nature of the legislation or policy determines political interrelationship among key actors. Policies that allocate jobs and contracts to congressional districts tend to receive broad political support, whereas legislations that aim at redistributing resources to the needy population are politically polarized.

Federalism in the United States tends to complicate documentary analysis, because many governmental decisions are dispersed across states and cities, and contextual variations tend to challenge research efforts to generalize the findings from a few study sites. At the same time, local variations offer an opportunity for experimentation. Researchers of urban reform are keen on analyzing mayors’ state-of-the-city speeches as well as city council minutes and voting outcomes. In public education, there are fifty state systems that define their own academic standards, and more than 14,000 locally elected school boards that govern their schools. Studies on school governance have drawn on school board minutes, collective-bargaining agreements, administrative guidelines, financial audits, and evaluation reports. In the context of intergovernmental relations, the literature on policy implementation pays particular attention to the goals of legislation, the definition of eligibility, and the extent to which the intended services and benefits are delivered to the targeted populations (Pressman and Wildavsky 1973). Studies of the federal implementation of education policy have relied on audit findings to identify if state and local agencies are meeting the federal program expectations (Wong 1990).

As the boundary between government and civil society changes, researchers are likely to pay more attention to a broader range of documentary sources. A study of congressional hearings suggests the rise of citizen-based action groups in shaping the direction of the government’s role in social welfare since the postmaterialist era of the 1960s (Berry 1999). Using local newspapers as an information source are often used in conjunction with other data collection methods, such as interviews, surveys, and site observations.

source, one study analyzed two major newspapers in one large city to examine editorial support for mayoral control of public schools (Wong and Jain 1999). Further, human conditions can be depicted through the making of, the study of, and the use of documentary films. This type of documentary work is carried out at the Center for Documentary Studies at Duke University and at the Southern Oral History Project at the University of North Carolina at Chapel Hill.

Documentary studies are likely to continue to play a prominent role in social science research. There has been a rapid proliferation and democratization of documentary sources as the World Wide Web has become more accessible to the public. Public-opinion polls, news articles, congressional hearings, and state audits of agencies' performance, and for-profit organizations' performance, just to name a few, are now easily accessible through the World Wide Web. Archaeological sites and artifacts are often scanned into digitalized format for research purposes. The Internet search engine Google and some of the world's major university libraries formed a partnership to convert their entire collections into electronic formats that will be widely accessible. Traditional barriers to access, such as transportation cost, will no longer impede documentary research, both domestically and globally.

Finally, the politics of documentary analysis must be taken into consideration. Documents come from many sources, including public-regarding and interest-based organizations. More often than not, documentary sources, especially secondary analyses conducted by think tanks, reflect a certain bias. Too often, students overlook the need to cross-validate the content of the documents. Furthermore, for students who are interested in in-depth research, there is still a need to navigate the labor-intensive process of obtaining permission to use certain documentary sources from governmental agencies.

DOMINANT STRATEGY

DOMINO THEORY

The domino theory was articulated by President Dwight D. Eisenhower in an April 7, 1954, news conference in which he worried that if communism remained unchecked, the free world might endure “the ‘falling domino’ principle. [In that case] you have a row of dominoes set up, you knock over the first one, and what will happen to the last one is the certainty that it will go over very quickly. So you have the beginning of a disintegration [of democratic countries] that would have profound influences” (Eisenhower 1954, p. 382). According to that principle, a change in one country will “spill over,” setting in motion the political transformation of an entire region.

GEOGRAPHIC AND POLITICAL ORIGINS

Of particular concern to American leaders at that time was the ongoing crisis in southeastern Asia, where the loss of Vietnam could be expected to lead to eventual Communist domination of Thailand, Indonesia, and perhaps New Zealand and Australia (Gaddis 1982). The application of the domino theory, however, was not limited to southeastern Asia. The growing momentum of communism and the falling of dominoes animated national security debates over American policies toward Western Europe and Latin America as well. After the Eisenhower administration, the Democratic administrations of John F. Kennedy and Lyndon Johnson continued to believe that setbacks in southeastern Asia in general and Vietnam in particular would have dire consequences.

Fears of dominoes falling were based primarily on two mutually reinforcing concerns. The first was that if the United States failed to support an ally against Communist agitation, Communist movements in neighboring countries and their Soviet and Chinese sponsors would be emboldened. Communist success would breed success, and failure to stem the tide early would push...
countries out of the American orbit, with disastrous long-term consequences. Second, that perception of threat was amplified by concerns that the inability of an American-sponsored government to suppress domestic insurgents or outside provocateurs would signal that the United States could not be counted on as a reliable alliance partner. In that case the insecurities of allied countries and the demonstrated inability or unwillingness of the United States to help overcome them would lead countries to pull away from the United States. On both counts American decision makers feared that seemingly small reverses in peripheral countries ultimately would lead to a massive redistribution of cold war power as country after country fell to Communist pressure.

Although the rhetoric of falling dominoes most often was used to articulate the dangers from the unchecked spread of Soviet expansion, some noted that dominoes might be induced to fall the other way as well. Soon after the end of the World War II (1939–1945) conservatives in the Truman administration advocated “rolling back” Soviet advances in Europe. Although the lexicon of falling dominoes had not been coined yet, the basic logic was the same: It was hoped that American successes would demonstrate the power of the West and the poverty of the Soviet alternative. If that policy was successful, it was hoped that it might set into motion a counterdomino effect in which European Soviet-styled authoritarian regimes were felled by a mix of domestic and Western pressure. The Soviets’ continued de facto and then de jure domination of Central and Eastern Europe frustrated those early reactionary impulses to roll back the postwar status quo. Thereafter, the world’s dominoes were seen as leaning against the United States from the 1950s through the 1970s.

THE REAGAN AND SECOND BUSH ADMINISTRATIONS
Despite the absence of a positive theory of a Communist rollback for much of the cold war, the idea did not die. After the collapse of détente in the late 1970s, many conservatives called for the Reagan administration to roll back communism in Europe and especially in Latin America. The intellectual basis for American overt and covert involvement in a number of military conflicts in the region, notably the 1983 invasion of Communist-held Grenada, indicated continued support for the concepts found in domino theory. Specifically, it was believed that American weakness in Latin America would lead to further Communist advances, whereas American successes not only would reverse that process but perhaps would lead to conditions in which established Communist regimes might be rolled back and ultimately expelled from Latin America. Again, the key point was the belief that success breeds success and that small and even tangential victories early can have a snowball effect: Communist successes would increase the support for and allure of that centrally planned and authoritarian model, whereas American successes would reverse the trend and create conditions under which free markets and democracy could flourish.

The end of the cold war did not spell the end of the domino theory. In the first decade of the twenty-first century the Bush administration used the domino theory to motivate and justify its policies in the Middle East and the war on terror. The Bush White House feared that successes by Islamist groups such as Al-Qaeda threatened Western-friendly states and provided a recruiting tool for those opposed to American interests in that region. On the one hand, American and Western successes in routing those elements and spreading democracy throughout the Middle East would set in motion a liberalizing and democratizing dynamic that would bring peace and stability to an unsettled region. On the other hand, if the Islamists’ attacks on friendly governments and Western interests went unchecked, it would catalyze a counter-Western and counter-democratic movement. According to the logic of the domino theory, the early victors in that struggle would prove their worthiness to be emulated and draw further recruits and converts to their cause; the losers would see their losses compounded as the struggle continued.

Again, the key assumption was that success creates a self-sustaining momentum that will lead to the domination of the region by one side or the other. Implicitly or explicitly that logic was given scholarly support by many “offensive” realists, such as William Wohlforth, who argued in 1999 that American willingness to serve as a leader and a supporter of democracy and free markets will lead to a pax Americana: a new era of American dominance and peace and cooperation.

CRITICISMS
The fact that the logic of domino theory has proved enduring does not mean that it is without critics. “Defensive” realists such as Kenneth Waltz (1998) and Christopher Layne (1993) argue that the success of a country holds within it the seeds of failure. They claim that as a country becomes more powerful, it threatens the sovereignty and autonomy of its neighbors, increasing their willingness to resist further expansion. Rather than going from strength to strength, aggressive countries encourage others to unite against them, and thus early successes make future expansion less rather than more likely.

According to the logic of balancing, early Communist success in southeastern Asia made countries such as Thailand and Japan more likely to support the
United States and pushed them farther from the Communist camp. Likewise, successes by Islamists are likely to drive states into closer cooperation with the United States out of fear that they could be next. At the same time, American activities in the region, such as the invasion and occupation of Afghanistan and Iraq, are likely to drive those governments away as they become increasingly wary of American power and influence. The defensive realist analysis thus turns the domino theory on its head. If it is correct, it should serve as both a comfort to American decision makers combating Islamists in the Middle East and a warning to those who would use American hegemony to launch a program of liberalization and democratization abroad.

DOPAMINE
Dopamine is a neurotransmitter that serves as a chemical messenger in the nervous system and permits individual nerve fibers (neurons) to communicate with each other. The dopamine neurotransmitter belongs to the class of compounds known as monoamines, and more specifically to a subclass of chemicals called catecholamines. Dopamine can act either as an inhibitory mechanism or an excitatory mechanism in the nervous system, depending on the location of dopamine neurons, and the receiving characteristics of the next neuron in the chain.

Dopamine activation has long been associated with increased motor output (i.e., increased physical activity) (Wise 2004). Hence, it is not surprising that dopamine depletion is associated with a variety of movement disorders, such as Parkinson’s disease. Characterized by tremors, muscle rigidity, and lack of fine motor skills, Parkinson’s is caused by a degeneration of dopamine projection fibers originating in a brain region called the substantia nigra. The fact that the administration of a substance (L-DOPA) that increases dopamine synthesis in this brain region is the primary approach to treating Parkinsonism underscores the importance of dopamine in the regulation of motor control and movement.

Changes in dopamine activity also are linked to the expression of certain psychological disorders, such as schizophrenia. Schizophrenia is characterized by shifting, illogical thought patterns, delusional thought processes, and hallucinations. The dopamine hypothesis of schizophrenia suggests that higher than normal levels of dopamine in the midbrain region of patients suffering from schizophrenia produce a biochemical imperative to engage in disordered behavior. Consistent with this position, the most commonly prescribed, and arguably the most effective, drug therapies for schizophrenia are dopamine receptor blockers. A compound labeled chlorpromazine (trade name Thorazine) is especially effective in reducing the symptoms of schizophrenia, and such dopamine antagonists when continued after treatment substantially lessen the chances for relapse compared to cases in which patients stop taking the drug.

There is evidence that blockade of dopamine transmission is associated with the devaluation of incentive systems, perhaps by affecting memory consolidation (Robbins and Everitt 2006). For instance, it is known that stamping-in of stimulus-response associations is blunted under conditions of reduced dopamine activity. Even once a behavior is learned, evidence shows that the ability to retrieve previously acquired information is reduced. Although the precise mechanisms responsible for these challenges to associative processes is not clear, it is clear that reward-seeking is diminished when dopamine systems are compromised.

There is a large literature that shows that a variety of rewarding events elevate the levels of dopamine in pleasure pathways of the brain. There are three major systems that are rich in dopamine fibers: the nigrostriatal system, the mesolimbic system, and the mesocortical system. Of the three, the pathway that has received the most attention from investigators of reward systems is the mesolimbic pathway. The dopamine projection neurons of the mesolimbic system originate in the ventral tegmental area of the midbrain and terminate in several forebrain regions, most importantly the nucleus accumbens. At one time it was believed that the nucleus accumbens constituted “reward central” and any events or substances that increased dopamine activity in this region served as rewards (Wise and Bozarth 1987). It is now known that
other pathways and neurotransmitters are involved in defining reward properties, but the scientific community still maintains that elevated levels of dopamine in the nucleus accumbens contribute prominently to the rewarding effects associated with a variety of motivational processes, including the sex drive and hunger (Berridge and Robinson 1998).

Although dopamine plays a role in mediating a broad array of reinforcing (reward) activities, the topic that has been studied most is the modulatory role played by dopamine in determining the rewarding effects of psychoactive drugs. While dopamine is important for drugs such as heroin, marijuana, and alcohol, it does not appear to be crucial with respect to determining the reward value of these types of drugs. It is certain, however, that dopamine is the major neurotransmitter involved in defining the potency and addiction potential of psycho-stimulants such as cocaine and amphetamine. With respect to cocaine, the drug blocks the action of the dopamine transporter (DAT) in the nucleus accumbens. DAT is the reuptake chemical in the synaptic cleft (space between neurons where neurotransmitters are released) that moves dopamine back inside the releasing neuron and restores dopamine levels. When DAT is blocked by cocaine, dopamine remains in the cleft and continues to stimulate the postsynaptic neuron, thus producing euphoria. Amphetamine operates similarly to block dopamine reuptake, but also increases the frequency and amount of dopamine release.

DORNBUSCH-FISCHER-SAMUELSON MODEL

The Dornbusch-Fischer-Samuelson (DFS) model of international trade was introduced into the economics literature by three Massachusetts Institute of Technology (MIT) professors in 1977. The model extends the widely accepted theory of comparative advantage of classical economist David Ricardo (1772–1823) to a conceptually infinite number of commodities, and the model integrates money and payments into what essentially had been a barter model. From DFS, greater understanding can be gleaned of the determinants of international trade patterns.

The model assumes the traditional classical framework of two trading countries and of labor being the sole factor of production. Suppose the countries are A and B. Country A exports any good where the wage rate for A’s workers (WA) multiplied by the labor time needed to produce a unit of the good (LA) is less than the wage rate for B’s workers (WB) multiplied by the labor time needed to produce a unit of that good in B (LB); that is, A exports any good where WA · LA < WB · LB. Country A imports goods where WA · LA > WB · LB. Expressed alternatively, country A will export goods where (WA/WB) < (LB/LA) and import goods for which (WA/WB) > (LB/LA), and, in DFS, a continuum of goods is specified in descending order of (LB/LA). (It is assumed for simplicity in this discussion that there are no transport costs and that the exchange rate is fixed at one unit of A’s currency = one unit of B’s currency.) Thus, if the wage ratio (WA/WB) is given, an examination of labor times can determine which goods in the continuum will be exported from A to B and which from B to A.

But what determines the wage ratio? As noted above, (WA/WB) would, when compared with the (LB/LA) ratios, determine the trade pattern; however, the trade pattern itself would also determine (WA/WB). For example, if the trade pattern is such that most of the different goods are exported from A to B and few goods are exported from B to A, then, in essence, there is strong demand for A’s goods (and therefore for A’s labor) and a trade surplus for country A. This demand for A’s labor will bid up WA relative to WB. As WA rises, some goods previously exported from A to B [because (WA/WB) < (LB/LA) for those goods] will no longer be exported but will be imported by A because (WA/WB) has increased.

With this interaction of the trade pattern and wage rates, an equilibrium trading pattern is established. Equilibrium occurs with balanced trade (exports = imports for each country) and, for the borderline good in the continuum between the goods exported by A and those exported by B, (WA/WB) = (LB/LA). All goods where (WA/WB) < (LB/LA)—the goods with higher (LB/LA) ratios—will be A’s exports. All goods for which (WA/WB) > (LB/LA)—the goods with the lower (LB/LA) ratios—will be B’s exports. The original DFS article then introduced transportation costs, nontraded goods, and exchange rate and other considerations, but the major...
contribution was this simultaneous determination of relative wage rates and the trading pattern.

From this equilibrium position, the impact of changes in various economic elements can be analyzed. For example, suppose that all consumers turn their tastes relatively away from A’s goods and toward B’s goods. The new demand for B’s goods will increase the wage rate in B relative to the wage rate in A, a change that will cause some of B’s export goods to become A’s export goods. At the new equilibrium, balanced trade will be restored, country B will be exporting fewer different goods than originally, and B’s wages will have risen relative to A’s.

Consider next the perhaps surprising consequences of a uniform productivity increase in all of country A’s industries. With this productivity increase, LA (labor time needed for one unit of output) falls in each of A’s industries, and there will be a greater number of different goods exported from A to B than previously (because (LB/LA) will now be greater than (WA/WB) for some goods for which (LB/LA) was formerly less than (WA/WB)). However, with more demand for A’s goods, (WA/WB) will rise and some of the new exports from A will revert back to being imports from B. In the model, though, the end result is that, on net, the number of different goods exported from A has increased and (WA/WB) has risen. Real income has increased in A, as its wages have gone up while the cost of producing its goods has gone down. Importantly, though, real income in country B also has risen. Even though B’s wage has declined relative to A’s wage, B’s absolute income has risen because the productivity increase has made B’s imports from A less expensive. Hence, a significant lesson from DFS is that productivity improvements under competition get transmitted across country borders—there is no absolute gain by one country and corresponding absolute loss for the other country.

The original DFS model has formed the basis for a number of extensions. Rudiger Dornbusch, Stanley Fischer, and Paul Samuelson themselves (1980) later incorporated a second factor (capital) into the model in a Heckscher-Ohlin framework and produced further conclusions. (Heckscher-Ohlin [or alternatively, Heckscher-Ohlin-Samuelson] refers to a standard trade model based on relative factor endowments of countries and relative factor intensities in the production of commodities.) The DFS model also has been extended, among much other research, in its Ricardian formulation to more than two countries in growth and customs union contexts (Wilson 1980; Appleyard et al. 1989) and into a multicountry framework, combined with monopolistic competition and econometric work, in its Heckscher-Ohlin formulation (Romalis 2004). A considerable amount of empirical work over the years has supported the relationship between labor productivity/costs and trade patterns predicted by the classical economists and DFS, a comprehensive example being Wendy Carlyn, Andrew Glyn, and John Van Reenen (2001). Criticisms of the model can be directed toward the realism of its assumptions of perfect competition and of smooth adjustment to technological change and other disturbances.

DOUGLASS, FREDERICK 1817–1895

Born into chattel slavery on February 14, 1818, in Tuckahoe on the eastern shores of Maryland, Frederick Augustus Washington Bailey, later known as Frederick
Douglass, Frederick

Douglass, created in his time and for future generations one of the most remarkable personalities in American history. As a public figure, Douglass rose through the brutalities of slavery to become at the time of his death on February 20, 1895, the most famous black American in the world and black America’s foremost intellectual voice.

Douglass’s preeminence in American history is gleaned from his direct contacts with the antebellum abolitionist leadership of William Lloyd Garrison (1805–1879), the suffragist leadership of Susan B. Anthony (1820–1906) and Elizabeth Cady Stanton (1815–1902), the militancy of John Brown (1800–1859) and Martin Delany (1812–1885), his meetings with U.S. presidents from Abraham Lincoln (1809–1865) to James Garfield (1831–1881), and his government assignments as U.S. representative to the Dominican Republic and Haiti. However, there is a private side, of which too little is made, to Douglass’s determination to engage the forces of evil, as he saw them, and to form alliances only when it was necessary for him to be heard by more people, read by more citizens, or at times, to present himself to another country, as he did on several occasions on his visits to the British Isles.

Douglass escaped from slavery in 1838. As his biographers have noted, in 1841 the former slave joined the Massachusetts Anti-Slavery Society under the leadership of Garrison, then leader of the radical wing of abolitionism and editor of the successful abolitionist newspaper, the Liberator. Douglass clearly modeled some of his behavior on Garrison. Both recognized the fiery spirit in each other, and both were orators connected by a passion to eliminate slavery. Through Garrison’s group, Douglass earned money as a speaker, widened his circle of abolitionist acquaintances, and traveled to new places. The most compelling event in 1845 from an abolitionist’s perspective was the publication of Douglass’s first autobiography, Narrative of the Life of Frederick Douglass, an American Slave, Written by Himself. Garrison, in fact, wrote the preface. Douglass later wrote My Bondage and My Freedom (1855), and in 1881 he published Life and Times of Frederick Douglass, his final autobiography.

The Narrative made Douglass famous and started a long and distinguished career for this brave man, prolific writer, and articulate democratic voice. In page after page, he details the painful and violent experiences slaves faced as they were raped, murdered, bought, and sold away from their families. Douglass not only named the murdered, he named the murderers who went unpunished as well, thus providing graphic proof that no law protected slaves against these crimes. Furthermore, his writing critiqued the structure of authority by slicing through the rhetoric of the state to expose slaveholders, especially those professing religious faith, in their role as personal agents in a system of slavery allowed to exist simultaneously with the ideals of a free republic. The Narrative established him as a reliable and serious source for presenting any of the issues of his day requiring instruction and correction, most of them related to slavery.

By 1847, as the editor of the second black-owned newspaper in the United States, the North Star, Douglass had found that the uses of history enabled him to move back and forth between his private and public worlds. Douglass’s use of history permitted him to speak about the signs of the times; it served, furthermore, to help him to judge civilization’s behaviors for failing to subject the nation’s moral faults to critical reflection. In this way, Douglass used history to critique reason. For him, the realities of slavery placed the present and the future of the United States in an untenable position: The country could not survive if it remained both slave and free. The purpose of Douglass’s legacy to America and to the world is to uphold the principle of freedom as an inalienable human right.

Although supportive of each other, Douglass and Garrison split over the issue of the Constitution as a document that supported the institution of slavery. As early as 1851, the relationship between the two became strained as Douglass, having studied the debate over the Constitution, rejected Garrison’s position that the Constitution was proslavery, whereas Douglass gradually saw the document as having the potential to eradicate slavery. Biographers have portrayed the breakup in Freudian terms as Douglass’s rejection of Garrison as a father figure and his search for his own identity. It is also important to note that freedom for Douglass encompassed a deep, multilayered view of the self that had more to do with being “self-made” than with being a collaborator. His understanding of the Constitution, ultimately, had less to do with what Garrison asserted than with what Douglass realized through his own complex social and historical understanding of the place of all humankind, black and white, male and female, in a democratic social order.

Having been a slave, Douglass instinctively understood the political rights of women. Their demand for equal citizenship and the right to vote found him using his considerable oratorical gifts and intellect on their behalf. As one of the few men to attend the 1848 convention on the rights of women in Seneca Falls, New York, the editor of the North Star added to the masthead of the paper his now-famous conviction, formed at this political gathering: Right is of no sex; truth is of no color; God is the father of us all and we are all brethren. He understood that the criticisms leveled against women in their pursuit of freedom against male supremacy were the very same arguments used against the freeing of slaves. While his dedication to women’s political rights never wavered,
Douglass did not always support the feminist leadership of Anthony and Stanton. They all supported civil war, but differed on other questions; for example, Douglass supported the Fifteenth Amendment giving black men the right to vote. Anthony and Stanton did not support this amendment because it did not offer the same rights to women.

In 1882 Frederick Douglass, now sixty-four-years old and known as the “sage of Anacostia” after the Washington, D.C., neighborhood where he lived, buried Anna Murray Douglass, his wife of forty-five years, who had long suffered from rheumatism. It was a considerable shock to the world when in 1884 he married Helen Pitts, forty-six, a white woman from a New York abolitionist family with deep roots in radical politics. The interracial marriage eliminated any distinction between private and public worlds: It clashed with social norms. Most whites and blacks, particularly members of the couple’s own families, looked upon the marriage as a violation, and neither family fully embraced them. Nevertheless, Douglass and Pitts lived happily and traveled to the great cities of Europe and to Egypt. After his death, and in the face of opposition from his children, she lectured and secured donations to preserve Cedar Hill, their home in Anacostia. The couple is buried in the family plot in Mount Hope Cemetery in Rochester, New York.

DOWRY AND BRIDE PRICE

Bride price and dowry are terms that refer to payments made at the time of marriage in many cultures, primarily in Asia and Africa. Bride price is typically paid by the groom or the groom’s family to the bride’s family. Dowry is typically paid by the bride’s family to the bride or to the wedded couple. Thus bride price and dowry are not necessarily the converse of each other. However, in the twentieth century, dowry payments in South Asia have increasingly been demanded by and paid to the groom’s family (and not just to the bride or the wedded couple). This suggests a usage of the term dowry to mean a *groom price*, the reverse of a bride price. Bride price and dowry need not be mutually exclusive, and marriage transfers in both directions can occur simultaneously. A complex set of norms may then govern the nature and the magnitude of payments in either direction.

PREVALENCE

Historically, the payment of bride price has been a more common occurrence than that of dowry. Only 3 percent of the cultures listed in Murdock’s *Ethnographic Atlas* (1967) demonstrate the practice of dowry payments, whereas 66 percent follow a norm of bride price. Dowries were common in the Near East, Europe, East Asia, South Asia, and some parts of the Americas. Although the custom of dowry payment has disappeared in most regions in the West, it remains widespread in South Asia. Bride prices were known to have prevailed extensively in Africa and also in areas of mainland, South, and East Asia, and North and South America.

Both dowry and bride price regimes were present in South Asia in the early part of the twentieth century; in the second half of the century, dowry amounts were inflated, including a switch from bride price to dowry in many areas where the former practice was dominant.

CHARACTERISTICS OF MARRIAGE PAYMENTS

The payment of bride price can take several forms. *Bride price* or *bride wealth* is typically a transfer in the form of livestock, goods, or money from the groom (or his family) to the bride’s kinsmen. *Bride service* refers to a transfer in the form of labor or other services rendered by the groom to the bride’s family. Both these forms of payment can be substantial in magnitude. In contrast, a *token bride price* is usually a small symbolic payment made by the groom’s family to the bride’s. Finally, *woman exchange* refers to the transfer of a sister or other female relative of the groom to the bride’s family in exchange for the bride.

A *dowry* or *groom price* is a payment made from the bride’s family to the bride, the groom, the wedded couple, or the groom’s family. It may consist of movable property such as money, ornaments, clothing, household goods, or cattle. In some cases land is also provided as a part of the payment.
The norms associated with marriage payments can be complex and vary largely across societies. These norms govern issues such as when the marriage payment is to be made and to whom, to what use the marriage payment may be put, and who inherits the payment in case of death or dissolution of the marriage. In some regions of South India, for example, a bride price is paid by the groom’s parents to the bride’s but must then be spent on the bride’s dowry. The payment may subsequently be claimed by the bride’s family, but only upon the death of the bride. In some African societies, on the other hand, the bride price received for a woman may be used to obtain a wife for her brother. But such a transaction is often regarded as a debt owed to the sister, and to repay it the brother must offer his daughter in marriage to her son.

FACTORS BEHIND MARRIAGE PAYMENTS

Many hypotheses have been put forward to explain the occurrence of bride price and dowry. One theory links marriage payments to the rights of inheritance held by women and explains dowry as a premortem bequest made to daughters. Another hypothesis links marriage payments to the economic value of women. Brides command a positive worth—a bride price—in areas where women make valuable contributions to agricultural work or other economic activity. In regions where women do not make an economic contribution, they constitute an economic liability and hence bring a dowry. A third hypothesis argues that marriage payments are “prices” that clear the marriage market—that is, these prices equate the demand for and supply of brides and grooms. Therefore, when grooms are relatively scarce brides pay dowers, and when brides are scarce grooms offer a bride price.

Other theories link the existence of different types of marriage payments to the laws governing marital and social ties (kinship structures). For example, bride price has been observed very often in societies with general polygyny (polygyny practiced by the general populace and not just the rich), whereas dowry almost always occurs in monogamous societies. Marriage payments have also been linked to norms of hypergamy—whereby brides are expected to marry into a higher caste or social group—and hypogamy—whereby brides are expected to marry into a lower caste or social group.

These and other explanations of marriage payments proposed by social scientists are not mutually exclusive, and more than one factor could contribute to the determination of marriage payments in any society. Moreover, because the combination of factors leading to dowry or bride price may be very different, the disappearance of one type of payment over time does not necessitate the appearance of the other.

DOWRY INFLATION AND THE MARRIAGE SQUEEZE IN INDIA

India witnessed a real inflation in dowries in the latter half of the twentieth century. Incidents of violence against brides who were unable to pay the dowries demanded of them (bride burning and dowry deaths) also became increasingly commonplace during this time, despite the passage of the Dowry Prohibition Act (1961), which made the payment of dowries illegal.

The phenomenon of the Indian dowry inflation appears especially perplexing given that the widespread practices of female infanticide and female feticide contributed to a highly masculine sex ratio in India throughout the twentieth century. It seems puzzling, therefore, that scarce women in India should have to pay increasingly higher prices for grooms. However, the nature of marriage payments is determined not by the overall sex ratio of the population, but the ratio of “marriageable” men and women. It is possible that this ratio is skewed in favor of women—leading to a positive price of grooms (i.e., dowry)—even when the overall sex ratio is skewed in favor of men.

The marriage squeeze hypothesis uses the idea of differential marriageable age of men and women to argue that population growth (which occurred in India in the 1930s) explains dowry inflation. The argument runs as follows: High rates of population growth lead to younger cohorts outnumbering older cohorts in the population. When older men marry younger women, this leads to an excess supply of marriageable women—or a marriage squeeze against women—causing the price of grooms to be bid up.

The norm of caste hypergamy, practiced in some regions of India, has also been invoked to explain the Indian dowry inflation. According to this norm, women must marry into a higher social class and hence pay a higher price for the more “desirable” groom. Alternative explanations of the dowry inflation point to Sanskritization (emulation, by lower castes, of the higher-caste practice of paying dowry), the changing economic value of women, and changing social structures in India during this time.

DRAKE, ST. CLAIR
1911–1990

John Gibbs St. Clair Drake was a University of Chicago–trained social anthropologist. He was born on January 2, 1911, in Suffolk, Virginia, to an African American schoolteacher mother and a Barbadian-born father who was a Baptist preacher and an international organizer for Marcus Garvey's Universal Negro Improvement Association.

After spending much of his youth in Pittsburgh, Pennsylvania, and Staunton, Virginia, Drake attended Hampton Institute (now Hampton University), graduating with a BS in biology in 1931. After graduation he spent a year in an experimental, nondegree program at Pendle Hill Quaker Graduate Center in Wallingford, Pennsylvania. The next three years he taught biology and English at Christiansburg Normal and Industrial Institute, a Quaker boarding school for blacks in western Virginia. In 1935 his former mentor at Hampton, Allison Davis, invited him to join his interracial team of anthropologists investigating racial caste and social class in Natchez, Mississippi. That project resulted in Deep South: A Social Anthropological Study of Caste and Class (Davis, Gardner, and Gardner 1941).

In 1937 Drake began graduate studies at the University of Chicago, where he worked with Lloyd Warner, Robert Redfield, and Fred Eggan. Drake's participation in a Works Projects Administration project in Chicago led to his collaboration with Horace Cayton, a sociology graduate student. Together they wrote the classic Black Metropolis: A Study of Negro Life in a Northern City (1945). The Chicago research project was also the basis for “Churches and Voluntary Associations Among Negroes in Chicago” (1940), a memorandum prepared for Gunnar Myrdal, commissioned by the Carnegie Foundation to produce An American Dilemma: The Negro Problem and Modern Democracy (1944).

In 1947 he conducted his dissertation research in Cardiff, Wales, where he studied a community made up of African seamen and their Welsh families. Drake examined the forms of social action that arose in response to British racial and colonial domination (Drake 1954). While in Britain he befriended Kwame Nkrumah (1909–1972) and other leaders of the African independence movement.

In 1946 Drake began a twenty-three-year tenure at Roosevelt University. Between 1954 and 1965 he pursued applied research interests during summers and two leaves. In 1954 and 1955 he collaborated with his wife, the sociologist Elizabeth Johns Drake (1915–1996), in a Ford Foundation–funded study of mass media in Ghana. From 1958 to 1961 he served as head of the Department of Sociology at the University of Ghana. He also directed research on the tensions between the postcolonial elite and traditional authorities, and on Tema, a modern port city built to stimulate Ghana's economic development.

The new city was populated by resettling villagers from traditional lands, and Drake's analysis of that contested process was both critical and understanding of the government's policy. During his Africa years, he advised Nkrumah and helped train Peace Corps volunteers, sensitizing them to the cultural and political factors likely to affect their work.

After Ghana's 1966 military coup, Drake's scholarly focus shifted to problems in the African diaspora: urban unrest and race relations in the United States; cultural retention, reinterpretation, and syncretism in the Caribbean; patterns of coping and resistance in the African diaspora; and the intellectual history of blacks in anthropology and in black studies. In 1969 he moved to Stanford University to direct its African and Afro-American Studies Program. After retiring in 1976, he produced the two-volume Black Folk Here and There: An Essay in History and Anthropology (1987, 1990), in the tradition of W. E. B. Du Bois's Black Folk Then and Now (1939). In this his last major work, Drake examined the cultural and intellectual history of antiblack prejudice in the precolonial Old World diaspora and the colonial diaspora that formed within the plantation societies of the New World. He presented a symbolic and textual analysis along with an intellectual history and sociology of the knowledge on the status of sub-Saharan Africans in ancient Egypt and the wider Nile River Valley, the Islamic and Judaic Middle East, Mediterranean Europe, and northern European Christendom. He explained the major shifts during the sixteenth century that led to the emergence of racial slavery. In this book, along with a series of seminal essays, he presented a paradigm for studying the African diaspora.
Influenced by black vindicationism, pan-Africanism, the Quakers, and Depression-era socialists and communists, Drake was an activist intellectual. He organized sharecroppers and tenant farmers in Mississippi and unemployed workers in Chicago. He campaigned against the University of Chicago’s urban renewal policy in the 1950s, and advised members of the Student Nonviolent Coordinating Committee (SNCC) in the 1960s. He was also a founder of the American Society for African Culture and the American Negro Leadership Conference on Africa. He died on June 14, 1990.

DRAVIDIANS

The Dravidians were the majority population across the Indian subcontinent before the second millennium. The evidence of early Dravidians comes from studying the Indo-Aryan culture, languages, and findings at many mounds, the preeminent of which are Mohenjodaro in Punjab and Harappa in Larkana District in Sind. The sources indicate an early Indian civilization with developments parallel to those of Mesopotamia and Sumeria. Excavations from the 1920s found craftsmanship that defines the Indus (or Harappa) culture of 5,000 years ago. The presence of spears, bows, and cattle suggests society’s transition from a matriarchate to a patriarchate state. For transactions they used seals as coins, some of which depict a prototype of the god Shiva.

Dravidians had an advanced city culture more ancient than the Aryans, who, as Indian legends tell and some dispute, invaded India from central Asia in several waves around 1500 BCE. The Rig Veda, an ancient Hindu scripture, records the destruction of Harappa, then called Hariyopiyah (5.27.5). In particular, the Aryan invaders targeted for extinction the Dasyus tribe, who were dark-skinned—a Dravidian feature. Yet another view indicates that the Harappa culture was already disintegrating when the Aryans arrived, perhaps due to natural causes such as a flood.

Among the jungle tribes in the Indus Valley were the Bhils, Kols, Santals, Kukis, Todas, and Oraos, some of which were Dravidians. One theory is that the Dravidians escaped into the hills after the first Aryan invasion, making the hills the safe ground for the Dravidians. The Aryans, being familiar with farming and cattle breeding, had the incentive to clear the lowlands in cooperation with the Dravidians. Thus, savannas and fens were transformed into rice fields. In this civilization building, the Aryans contributed knowledge of horse-power, iron, and the distinct Sanskrit language to the Harappan oxen-force, copper, and the difficult to define Dravidian language.

The link between the Harappan language and the Dravidians is controversial. One theory holds that the Harappans used a sign language that is not alphabet-based, as in Sanskrit, whereas others maintain that the Harappan language is close to the Dravidian language. The proto-Dravidian language was placed at the scene of the Harappan culture. The prominent language groups of the Dravidians today are Brahve in the north, Gonds in north and central India, Kannadigan in Karnataka and Maharashtra, Malayali in Kerala, Tamil in the South, and Telugu in Andhra Pradesh. Inscriptions at Harappan sites suggest a resemblance to the old Tamil that is spoken by Dravidians in southern India today. Geneticists are now

DREAMING

Dreaming is an episodic activity of the sleeping mind during which spontaneous sensory experiences occur that are perceived at the time as if real. Although dreaming is common, occurring in all humans, the dreams themselves are unique, based on each person’s own memory bank of images, a residue of their particular life experiences. The meaning and purpose of dreaming has been a source of speculation over the course of history. It was not until 1900, when Sigmund Freud (1856–1939) published *The Interpretation of Dreams*, that there was a comprehensive theory that placed dreams as centrally important for the understanding of waking behavior. This theory formed the basis of the psychoanalytic treatment method, which relied on patients’ recall of and associations to their dreams.

Dream interpretation dominated the practice of psychiatry for the next fifty years. The key to their understanding rested on Freud’s model of the mind as operating on three different levels—the conscious, preconscious, and unconscious—with all three influencing waking behavior. The conscious mind is what is in awareness in the moment; the preconscious consists of mental representations that, although not in immediate awareness, can be brought to consciousness voluntarily; the unconscious material, while not accessible by an act of will, is a major source of dream scenarios. The unconscious contains the remains of early childhood experiences related to learning to control basic impulses (particularly those of sex and aggression) and to express these only in a socially appropriate fashion. These powerful instinctual drives remain active throughout life and cause anxiety if they threaten to become conscious. They are controlled during waking by defenses, the learned ways of keeping them out of consciousness. These defenses are weakened during sleep, when the danger of a breakthrough into action, which would cause internal guilt or external punishment, is reduced due to our inability to act while sleeping.

Freud believed that dreams allow the mind to hallucinate the fulfillment of these prohibited impulses safely, without the risk of consequences. Because the risk, though lowered, is not completely absent during sleep, and to ensure that the sleeper is not shocked into wakefulness, dreams express these wishes in disguised forms. Thus, dreams require some expert interpretation to decode their true meaning. Freud distinguished the dream story, called the manifest dream, from its underlying or latent meaning, which refers to the unfulfilled instinctual wishes. The latent meanings can only be expressed symbolically to allow their safe gratification. The interpretation of dreams thus became the basis for understanding patients who came for help with emotional problems of overcontrol or undercontrol of their impulse-related behavior.

A challenge to this view followed the discovery in the 1950s of the close association of rapid eye movement (REM) sleep and the experience of dreaming. By monitoring the brain waves, eye movements, and muscle tone of persons observed while sleeping in a laboratory, three to five episodes of REM sleep could be identified each night. If the sleeper were then awakened at these times and asked to report what he or she had just been experiencing, 85 percent of the time the sleeper would describe a dream. The regularity of REM sleep, occurring approximately every ninety minutes, allowed a more complete sampling of dreaming than had ever before been available. Many people have no recall of their dreams, and even those with good recall rarely remember more than one per night. The sleep laboratory technique opened the door to studies of the continuity of a theme from first dream to last, and of the relation of the dream content to some waking, emotion-arousing stimuli, such as a frightening or sexually arousing movie, or an experimentally induced change in a basic need, such as thirst by depriving sleepers of water beforehand. For the most part, these studies showed that dreams are difficult to influence and more often follow their own agenda.
The finding that REM sleep is turned on periodically, starting at the primitive brain structure called the pons, further challenged Freud's view. Dreams could not have any inherent meaning if they spring from the nonthinking pons. The activation-synthesis hypothesis of dreaming, proposed in 1977 by J. Allan Hobson and Robert McCarley, explained the apparent (manifest) meaning of a dream as an afterthought, most likely resulting from associations to the sensory images, which are accidental, triggered by the activation of a brain pathway that flows upward from the pons to the visual association areas of the cortex. These images are then linked into a dream story under the influence of the ongoing emotional concerns of the dreamer. In this way dreams are given meaning in the same way as are waking stimuli, when what we see is colored by the present state of our needs and interests. This theory robbed dreams of any special meaning and had a generally dampening effect on dream research for the next twenty years.

The resurgence of interest in dreaming is partly due to the development of sleep disorder centers, which attract patients with dream disorders, such as the repetitive nightmares of those suffering from posttraumatic stress disorder. The resurgence of interest is also partly a result of the development of more sophisticated technology. Brain imaging methods allow a closer look into the areas of the brain activated when REM sleep is ongoing. Using this technology, differences between those areas that are more active in REM sleep than in non-REM sleep or waking confirm that during REM the brain is more intensely active in areas related to instinctual behaviors (hypothalamus and basal forebrain), the emotional areas (limbic and paralimbic), and the visual association areas of the cortex. Activity is lessened during REM in the areas associated with the executive functions: thinking and judgment (the prefrontal cortex).

Brain imaging studies are looking into differences between REM sleep in normal persons and in those with various psychiatric diagnoses. This method has illuminated the abnormality of REM sleep of those suffering from major depression. These patients, when most symptomatic, have increased REM sleep but greatly reduced recall of any dreaming. Their imaging studies show more activity in the emotional areas (limbic and paralimbic) than do nondepressed persons, and heightened activity in the executive cortex. Perhaps these patients are flooded with negative emotion but are overcontrolled in its expression. In Freud’s terms, the dream function has failed to allow gratification of unconscious wishes. Without dreams these patients would be difficult to treat psychoanalytically and require another approach.

DRED SCOTT V. SANFORD

Dred Scott v. Sanford (1857) was a major U.S. Supreme Court case dealing with the status of slaves in the United States. In trying to understand the Dred Scott decision today, it is important to point out that African Americans and white Americans see the society in which they live very differently. Contemporary studies by sociologists of race and ethnicity, using public opinion data, continue to show significant racial gaps in the perceptions of racism as an issue. For example, a 2005 Gallup poll indicated that 57 percent of African Americans believed that “black-white relations will always be a problem,” but only 45 percent of whites agreed. Furthermore, this racial gap has increased rather than decreased since the 1960s. These data are important in relation to the Dred Scott decision and its legacy because they suggest that white Americans and African Americans view this continuing legacy differently. Though the case was decided in the mid-nineteenth century, the Dred Scott decision is not irrelevant in contemporary race relations in the United States.

Dred Scott (d. 1858) was a slave who sued his owner for freedom in 1847 based on the fact that during the period in which she owned him she had moved him from state to state, passing through the “free states” of Illinois and Wisconsin. The case was in the court system for a decade before it finally reached the U.S. Supreme Court in 1857. Five of the justices who decided this case were from slave-holding families. Chief Justice Roger B. Taney (1777–1864), speaking for the Court in 1857, wrote that:
They [slaves] had for more than a century before been regarded as beings of an inferior order, and altogether unfit to associate with the white race, either in social or political relations; and so far inferior that they had no rights which the white man was bound to respect; and that the negro might justly and lawfully be reduced to slavery for his benefit. He was bought and sold, and treated as an ordinary article of merchandise and traffic whenever a profit could be made by it.

There were four main judicial outcomes from this case. First, this ruling established that slaves were to be enslaved for life: They could not purchase or sue for their freedom, even if they had lived for periods of time in “free states.” Second, this case codified a long-standing belief that slavery was solidly grounded on the “fact” that people of African descent were not fully human. In fact, in another part of this case, the Supreme Court ruled that for taxation and voting purposes slaves constituted only three-fifths of a human life. Though the intent of this ruling was to deny slaveholders power (by devaluing their human property), the ideological outcome was twofold: (1) It served to reinforce the devaluing of people of African descent (slaves) as a fraction of a person; and (2) it reinforced the practice in which people of African descent were held as chattel, no different from cattle—that is, slaves could legally be held as property and their value could be debated and assigned. Third, people of African ancestry, slave or free, could not become citizens of the United States and could not sue in federal court. Fourth, the denial of citizenship prohibited slaves from entering into legal contracts. The implications of this decision set in place barriers that included prohibitions on purchasing land (which is critical to the establishment of wealth), as well as prohibitions against family formation based on civil contracts, namely marriage and adoption, and finally voting.

Interpreted sociologically, Dred Scott is a negative legal decision that had continuing legacies for African American civil society. The Dred Scott decision was wrong in 1857, and in response to the pounding of the abolitionist movement, the decision was effectively overturned through the implementation of the “Reconstruction Amendments,” the Thirteenth, Fourteenth, and Fifteenth Amendments to the U.S. Constitution. These historic developments eventually opened the opportunity structure for African Americans, even if only slightly.

The impact of the Dred Scott decision is twofold. First, the section of the decision that ruled that African Americans are less than fully human set the ideological tone for 150 years of discrimination, from Jim Crow–style segregation to the continued and documented discrimination that African Americans face in education, employment, and housing (Bajaj and Nixon 2006; Bonilla-Silva 2006). The systematic and brutal segregation and discrimination by whites of African Americans would not have been so widespread and long-lasting if white Americans believed African Americans were fully human and similar to themselves.

Second, the Dred Scott ruling concluded that African Americans had no rights worthy of recognition by whites, specifically the rights associated with citizenship and accorded to all other Americans. This set off a series of voter disenfranchisement laws in the decades following the decision, especially in the South, that were designed to deny African Americans the right to vote. Florida, for example, enacted such a law in 1868 (Earls and Mukamal 2006; Shofner 2001).

Debates about the long-term effects of the Dred Scott decision are contentious. Bruce Sacerdote (2005) argues that the descendants of slaves “caught up” to those of free blacks within two generations, at least in terms of schooling and literacy. In contrast, William Darity, Jason Dietrich, and David Guilkley (2001) document the direct economic effects of Jim Crow segregation into the 1980s and 1990s. This debate is similar to another contentious issue in the United States: affirmative action. Some scholars argue that affirmative action policies have leveled the playing field between whites and African Americans, whereas others suggest it will be many years before affirmative action will have accomplished its goal.

Such empirical evidence indicates that the Dred Scott decision (1) provided support for long-standing beliefs in the racial inferiority of African Americans that were commonly held by white Americans, and (2) laid the foundation for a series of disenfranchisement laws that prohibited African Americans from taking advantage of one of their citizenship rights—the right to vote.

Drought

Drought is a feature of climate that is defined as a period of below-average rainfall sufficiently long and intense to result in serious environmental and socioeconomic stresses, such as crop failures and water shortages, in the affected area. Droughts can occur in any climatic region, but their characteristics vary considerably among regions. What droughts in all climatic regions have in common is their gradual onset, which—in contrast to other natural hazards—makes their beginning and end difficult to identify. Defined primarily as natural phenomena, droughts have not received much attention in the social sciences. Only since the 1990s, with the increasing appreciation of the linkages between the environment and society, have droughts begun to be viewed as an issue of interest also for the social sciences.

Drought is caused by the sinking motion of air in a high-pressure cell, which results in decreasing relative humidity of the air and little or no precipitation. Most climatic regions are temporarily under the influence of high pressure; droughts occur only when atmospheric circulation patterns that cause the high pressure persist or recur persistently over an unusually long period of time. Because of the global nature of atmospheric circulation, explanations for anomalous circulation patterns extend far beyond the drought-affected area. Thus global patterns of atmospheric pressure systems and sea surface temperatures have been invoked to explain the occurrence of periodically recurring drought events in some parts of the globe. Most prominent among those global patterns is the El Niño Southern Oscillation (ENSO), a coupled ocean-atmosphere anomaly that originates in the Pacific basin but has repercussions on the climatic conditions in areas as far apart as southern Africa, India, and Brazil. Anthropogenic processes that lead to changes in land cover, such as deforestation and overgrazing, affect local-scale moisture recycling and can induce local reductions in rainfall. Although simulation models have shown the possibility of substantial reductions in rainfall resulting from land-cover change, anthropogenic disturbances large enough to explain more than local-scale reductions in rainfall have not been observed.

TYPES OF DROUGHT

The effects of drought on environment, economy, and society are manifold. In order of the increasing severity and scope of their impacts, four types of drought are commonly distinguished: A meteorological drought manifests itself in a shortfall of precipitation or changes in precipitation intensity and timing, possibly aggravated by other climatic factors, such as high temperatures and winds. Risks associated with this type of drought include wildfire hazard and reduced water infiltration into the soil. If the drought persists long enough to result in significant soil water deficits and plant water stress, it crosses the threshold into an agricultural drought. Lower crop yields and quality, as well as increased soil erosion and dust emission, are possible impacts expected from this type of drought.

Because various crops differ in their water demand, a farmer’s choice of crop type can either buffer or exacerbate the effects of an agricultural drought. A drought is classified as a hydrological drought once the precipitation shortfall affects surface and subsurface water supplies. Hydrological droughts usually lag behind the occurrence of meteorological droughts because of the time needed for precipitation deficits to reach the surface and groundwater levels of the water cycle. Their impacts, which consequently are also out of phase with those of a meteorological and agricultural drought, include reduced stream flow, below-normal reservoir and lake levels, loss of wetlands, and declining water quality. Although climate is the primary factor of a hydrological drought, humans contribute to its effects by changes in land and water use, such as urbanization and the construction of dams. Finally, a socioeconomic drought occurs when the supply of economic goods and services, including water, forage, food, and hydroelectric power, can no longer be met for drought-related causes. Farmers and ranchers, who depend on agricultural and pasture productivity, are the first to suffer losses. Then follow industries depending on agricultural production. As a result, consumers may have to pay more for their food and other weather-sensitive products and services.

The socioeconomic effects of a drought vary not only in proportion to the severity of the climatological event but also depending on the vulnerability of the affected...
Drought

Monetary costs arise for any economy hit by drought, such as to cover for lost crops, crop insurance payouts, and fire damage; but only in the most vulnerable populations of the developing world are drought effects—food insecurity, famine, health problems, and loss of life and livelihoods—often paired with economic, social, and political difficulties. Subsistence farmers and pastoralists in particular suffer from crop and livestock losses, as well as from increased food prices. Droughts force many of them to migrate from rural to urban areas, increasing pressure on resources there.

COPING WITH DROUGHT

Scientists and decision-makers have devised a number of ways to deal with drought, which can be grouped into drought monitoring, forecasting, and mitigation. Meteorologists around the world carefully monitor meteorological and hydrological variables (precipitation patterns, soil moisture, stream flow) over time to determine the onset and end of a drought. Satellite remote sensing technology has contributed immensely to quantitative monitoring over large geographic areas. Understanding the complex physical aspects leading to droughts is a prerequisite for making increasingly reliable and credible drought predictions. Empirical studies have shown that drought results from a complex interplay of different climatological factors, which makes forecasting difficult.

In the tropics, where scientists have made significant advances in understanding the climate system, the potential for seasonal drought predictions is promising, particularly with respect to droughts related to ENSO. Multiyear droughts as well as droughts outside the tropics still cannot be predicted with a level of accuracy that is without risk for the users of those predictions. Knowing the frequency, duration, and spatial extent of past droughts, however, helps in determining the likelihood and potential severity of future droughts.

In addition to the assessment of meteorological processes, drought mitigation also requires an understanding of the vulnerabilities of different population groups to drought. Mitigation tools range from early warning systems, which monitor both meteorological conditions and vulnerable populations (e.g., the Famine Early Warning Systems Network, operating in Africa, Central America, and Afghanistan), to various forms of weather-related crop insurance schemes (e.g., in the United States and Australia among others), emergency water supply augmentation (e.g., tapping new water resources), and water demand reduction (e.g., by means of economic incentives for water conservation, improvement of water use efficiencies, breeding for drought tolerance, diversification to less weather-dependent economic activities, and public water conservation awareness programs). As droughts are expected to become more frequent and more extreme with global warming, it is imperative to improve drought mitigation efforts and increase future drought preparedness.

MAJOR DROUGHT EVENTS

Major drought events in modern history include:

- China, 1877–1878: Provinces across northern China were depopulated as grain stocks ran out as a result of severe droughts. Millions of people perished from starvation.
- Soviet Union, 1921–1922: A fierce drought hit the Ukraine and Volga regions. The death toll reached almost five million people, more than the total number of casualties in World War I (1914–1918).
- United States, 1930s: The Dust Bowl drought, which ravaged the American and Canadian Great Plains in the 1930s, is considered one of the major droughts of the twentieth century. Coinciding with the Great Depression, it had major impacts on the United States and Canada, including a mass migration from the Great Plains to the western coast in search of better living conditions.
- West Africa, 1970s: The West African Sahel region experienced droughts of unprecedented spatial extent and duration, which created a famine that killed a million people and affected the livelihoods of more than fifty million. The great Sahelian droughts were also blamed for widespread environmental degradation of this dryland region.
- Ethiopia, 1984–1985: A severe drought, exacerbated by the government’s censorship of news of the emerging crisis, brought about famine and forced millions to leave their homes, triggering the world’s worst refugee crisis to date.

In 2005 Australia experienced a major drought coupled with above-average temperatures, with the southern agricultural areas particularly hard hit. In 2006 drought conditions prevailed across much of Europe—for Spain the most serious drought in more than a century—and caused water shortages for agricultural and tourism sectors. At the same time, China faced its worst drought in fifty years, with crop failures and deaths of cattle causing huge economic losses.

Drucker, Peter  
1909–2005

Peter F. Drucker was a writer, management consultant, and university professor. He was born in Vienna, Austria, on November 19, 1909. After receiving his doctorate in public and international law from Frankfurt University in Germany, he worked as an economist and journalist in London. He moved to the United States in 1937.

Drucker published his first book, *The End of Economic Man*, in 1939. In it, he describes the causes for the rise of fascism, including the failure of established institutions that led to its emergence. He joined the faculty of New York University's Graduate Business School as a professor of management in 1950. From 1971 until his death, he was Clarke Professor of Social Science and Management at Claremont Graduate University in Claremont, California.

Drucker consulted with dozens of organizations and executives around the world, ranging from the world’s largest corporations, such as General Motors and the General Electric Company, to entrepreneurial startups and various government and nonprofit agencies, such as the American Red Cross, Girl Scouts of the USA, and the Salvation Army. He devoted extensive time during the last two decades of his life to helping professionalize the management of large and small social-sector and nonprofit organizations. He wrote and spoke frequently of the need to revitalize and transform governmental organizations, and he advocated privatizing the delivery of government goods and services as much as possible.

Drucker’s most significant contribution was to codify management as both a discipline and a practice—he is widely recognized as the “father of modern management.” His second major accomplishment was to develop “innovation and entrepreneurship” as a systematic discipline and practice for the purpose of managing change in all of the institutions of society. This accomplishment was a continuation of his work in support of what he called “a functioning society.”

Drucker referred to himself as a “social ecologist.” Social ecology, he wrote, requires a “rigorous method of looking, identifying, and testing” for changes that are in the process of emerging in society (Drucker 1992, p. 62). Thus, a social ecologist tries to identify and define new developments that are occurring or that have already occurred. These developments, or discontinuities, appear gradually and may not be noticeable until they cause major impacts on society and its institutions. Drucker’s ability to identify and define new developments in the twentieth century was legendary, and it can be seen in almost all of his works.

Drucker first identified the emergence of knowledge work, the knowledge worker, and the knowledge society in his 1959 book *Landmarks of Tomorrow*. He identified an event that was very important to society—the shift from manual work to knowledge work in developed economies. He believed that organizations and executives needed to prepare themselves to manage and exploit this shift for the good of society and its citizens. He tracked the emergence of knowledge work for a half-century, tracking its emergence from a trickle to a major force in developed societies. He described this major force in his 1993 work *Post-Capitalist Society*.

A fair amount of the methodology Drucker used as a social ecologist is contained in *Innovation and Entrepreneurship*. This book “shows how one systematically looks to the changes in society, in demographics, in
meaning, in science and technology, as opportunities to make the future” (Drucker and Maciariello 2004, p. 4).

Valid criticisms of Drucker’s work have to do with his frequent use (or abuse) of data. With the exception of demographic data, Drucker often used data to make a larger point, for which the precision he specified was unnecessary. In addition, throughout his work, he generally under-referenced the works of other authors.

Critics have also argued that Drucker’s management is “utopian,” that it relies on an unrealistically positive view of human nature, human potentialities, and organizational potential. While Drucker knew of the human proclivity toward corruption—perhaps better than his critics, having seen firsthand the rise of Hitler and the rise of German anti-Semitism (see The End of Economic Man)—he chose to focus primarily on the more noble aspirations of human beings. Peter Drucker died of natural causes on November 11, 2005, in Claremont, California.

**DRUG TRAFFIC**

Drug trafficking (or distribution) refers to the production, selling, transportation, and illegal import of unlawful controlled substances such as marijuana, cocaine, heroin, methamphetamine, MDMA (ecstasy), LSD, and a variety of other “club drugs,” such as GHB and Rohypnol typically associated with the young adult “rave” dance-party scene. Trafficking laws, and punishments for their violation, vary according to drug type, the quantity seized, the location of the distribution (e.g., drug-free school zones), and whether minors were sold to or targeted. Drug trafficking laws can implicate a single individual or syndicates involving broad rings of people participating in organized illegal drug activity.

Drug trafficking and trafficking networks take many different forms that are specific to the type of drug involved, the geographic origin of the drug, the risk of detection by law enforcement, the level of competition for consumers in the marketplace, and the people to whom the drugs are being sold or distributed. In addition, recent studies have shown that the nature of drug trafficking and drug markets is affected by society’s perception of the particular drug and the types of people trafficking in the drug, often independent of how serious the drug is deemed by lawmakers (Mohamed and Fritsvold 2006).

Trafficking is the direct result of a political decision to criminalize particular substances that are in demand among members of a society. The illegal drug market in the United States has established itself as one of the most profitable in the world. Americans are the world’s largest consumers of cocaine, and they rank among the top consumers of other drugs, such as heroin, marijuana, and methamphetamine (CIA 2006). According to the U.S. Department of Health and Human Services (HHS), nearly 20 million Americans aged twelve or older were current illicit drug users in 2004, meaning they had used an illegal drug at least once in the previous last month. The HHS also reports that marijuana is the most commonly used illicit drug among Americans. In 2002, for example, the drug was used either alone or in combination with another illegal drug by 75 percent of current illicit drug users.

This high demand for drugs (in spite of their illegality) and the lure of profits are two of the primary reasons people knowingly enter into the drug trade. In the upper echelons of the international drug trade, political ambitions and influence are also motivating factors. However, for many people, particularly those at the cultivation and harvesting end of drug trafficking pipelines, the drug trade is merely a means of survival. For example, peasant farmers in Peru, Colombia, Bolivia, and Ecuador have been driven from traditional crops like coffee to coca cultivation, the plant from which cocaine is manufactured. For many of these peasants, coca is the only marketable crop they can produce to sustain their already meager lifestyles—a sustenance that amounts to about $750 to the grower for every 500 kilograms of coca leaves produced (Inciardi 2002).

**DRUG TRAFFICKING: A MULTINATIONAL PHENOMENON**

Most of the illicit street drugs consumed in the United States come from plants that are cultivated in the less developed nations of Latin America, Southwest Asia, and
Southeast Asia. Usually, when the plants reach maturity, they are harvested and go through a local refinement process that prepares them for trafficking to U.S. street drug markets. For example, most of the marijuana consumed in the United States originates in Mexico. As already discussed, the coca leaf from which cocaine is derived is primarily grown in the South American nations of Colombia, Bolivia, and Peru. The opium poppy, from which heroin originates, is grown in the Southeastern Asian nations of Afghanistan and Pakistan, the Southeastern nations of Myanmar and Laos, increasingly in Columbia and Mexico, and in a handful of other nations around the globe.

It is no coincidence that these less developed countries are the primary sources of the raw materials used to supply America’s illicit drug habits. Aside from being geographically conducive to opium poppy, coca, or marijuana cultivation, most of these nations have been overlooked by the global economy and resort to or tolerate drug trafficking as a means to gain an economic foothold through the estimated $400 billion a year international drug market. “As a consequence, whole nation-states—Bolivia, Colombia, Laos, Malaysia, Mexico, Pakistan, Peru, Puerto Rico, Thailand, and Turkey—depend upon opium, coca, and hemp production for their agricultural base, and the manufacture of heroin, cocaine, and marijuana is a significant productive sector of the economy” (Chambliss 2001, p. 101). In the relatively small-player South American nation of Guyana, cocaine traffickers earn an estimated $150 million every year, the equivalent of 20 percent of the country’s gross domestic product (Hutchinson-Jafar 2006).

For other participants in international drug trafficking, contempt for what they perceive to be a heavy-handed American foreign policy also plays a role in the funneling of drugs into the United States. The anti-Western Taliban regime in Afghanistan was believed to be largely funded by opium poppy cultivation. In the 1970s, Carlos Lehder Rivas emerged as a power broker in the notorious Medellin Cartel in Colombia. Lehder was known for being intensely anti-American, and he saw cocaine smuggling into the United States as a move toward political independence for his native Colombia (Inciardi 2002). In 2005, Evo Morales, the head of a federation of Bolivian coca leaf campesinos (simple farmers) who banded together to oppose U.S.-backed coca eradication programs, was elected president of the country. While Morales insists “I am not a drug trafficker” (BBC 2005), the vast majority of coca harvested in Bolivia and other Andean nations is not used for traditional cultural practices. Rather, the bulk of this coca is refined into cocaine for sale on the black market in the United States and elsewhere, and cocaine exports have historically provided Bolivia with more income than all of its other exports combined (Chambliss 2001).

Currently, the U.S.-Mexico border is the primary point of entry for cocaine shipments being smuggled into the United States, and approximately 65 percent of the cocaine smuggled into the nation crosses its southwestern border. But, before this cocaine reaches Mexico, it has typically made stops in several other countries whose drug traffickers play key roles in bringing cocaine to market. After the coca leaf is refined into coca paste, typically in remote locations somewhat close to where the coca is harvested, it works its way through Amazonia (the river valley and rain forest region covering 2.5 million square miles of South America) to Colombia, where it is refined into powder cocaine. From Colombia, the cocaine travels by air and sea through the Caribbean, Central America, Cuba, and Mexico on to the United States (Inciardi 2002).

Drug Traffic

On the international level, drug production, largely fueled by U.S. demand, has brought about the establishment of criminal syndicates that organize their law-breaking activities around drugs and jeopardize political stability in drug-producing nations. “The concentration of economic and paramilitary resources in the hands of outlaw trafficking ‘cartels’ has presented a serious challenge to governmental authority” (Smith 1992, p. 1). In many cases, drug traffickers resort to violence and other criminal activities to intimidate opponents, including law enforcement, and to protect and expand their market share. However, according to some experts, the claims of the strong-arm cartels have been somewhat overstated. With regard to Colombian cocaine cartels, Guy Gugliotta notes that the murder and intimidation of small drug traffickers and other dissenters by large traffickers in the late 1970s and early 1980s was largely mythological. While there was undoubtedly a great deal of violence perpetrated by these cartels, proprietary leverage was their greatest asset. “The large traffickers’ success as a cartel was probably due to a more mundane factor—the members controlled cocaine’s infrastructure . . . [and] had established vertically integrated processing networks that could move cocaine by the hundred-weight” (Gugliotta 1992, p. 112).

Nonetheless, for a variety of reasons, most of which stem from the illegality of illicit drugs, crime and violence are mainstays of the drug economy. Increased pressure by U.S. drug enforcement agencies and increased cooperation from international governments in the fight against drug distribution have driven traffickers to search for new smuggling routes into the United States. Many of these new routes, particularly those used to smuggle cocaine and marijuana, are in the Caribbean and contribute to increases in crime, violence, and political corruption in the region. In 2005, for example, drug-fueled violence
drove Jamaica’s murder rate to a record high. However, as smuggling routes become more stabilized and drug territory becomes more clearly distributed among those controlling the Caribbean drug trade, levels of crime and violence may level off and decline in the region.

In efforts to avoid the violence, vice, and property crimes associated with drug trafficking, several nations (and a few U.S. cities) have adopted formal or informal drug decriminalization policies, with some success. Chambliss found that a de facto drug decriminalization policy in Seattle, Washington, reduced crimes associated with drugs, particularly murder and other crimes of violence. One of the primary reasons for this reduction was decreased competition among black-market sellers, who typically employ violent measures to protect their drug dealing territory. The Netherlands, Spain, Denmark, Switzerland, Austria, and Italy have also experimented with formal or de facto drug decriminalization policies. These nations have found that crimes committed by addicts attempting to support their drug habits have declined, while other public health problems, such as HIV transmission, have decreased as well (Chambliss 2001). However, because of the enormous profits to be gained by high-level distributors from the supply of drugs, and because of the lack of viable economic opportunities for participants at the lower levels of the drug trade, illegal drug trafficking and the ills with which come it are likely to remain mainstays of modern society.

SEE Drugs of Abuse.

DRUGS OF ABUSE

Drugs of abuse are commonly classified by their pharmacological and behavioral effects into six categories: (1) opiate analgesics, (2) stimulants, (3) depressants, (4) hallucinogens, (5) inhalants, and (6) anabolic steroids. Most of these drugs mimic endogenous neurotransmitters that are naturally present in the human body and regulate certain processes within the central and peripheral nervous systems. Because the quantity of drugs consumed by abusers typically far exceeds the level that naturally occurs in the body, the effects on neurons can range from subtle changes associated with tolerance (i.e., reduced sensitivity) to cell damage or cell death.

Dependence liability refers to the risk that repetitive use of a drug will lead to physical or psychological dependence, also known as addiction. Alcohol and tobacco have by far the highest rates of documented physical dependence in the United States (see table 1). Moreover they have high dependence liabilities: Roughly one-third of individuals who repeatedly smoke tobacco will develop nicotine dependence, and approximately 15 percent of those who repeatedly drink alcohol will become alcoholic. These dependence liabilities are comparable to or exceed those of cocaine, stimulants, and heroin. Although it has been asserted that cannabis is not addictive, Alan Budney and John Hughes pointed out in a 2006 article that nearly one in ten people who smoke marijuana will come to satisfy diagnostic criteria for dependence, including compulsive usage and withdrawal symptoms of mild to moderate severity.
OPIATE ANALGESICS

Opiates are drugs derived from the opium poppy plant that have analgesic and sedative qualities commonly used to treat pain. Examples include opium, heroin, and morphine. Synthetic analogs of these drugs, which are called opioids, have been created in the laboratory. Examples include methadone, hydrocodone, and oxycodone. The short-term psychoactive effects of opioids involve euphoria, drowsiness, and impaired motor and cognitive functioning. Because opiates and opioids also inhibit activity in brain regions that regulate basic functions such as respiration, they can precipitate death by suffocation. The risks increase dramatically when these drugs are combined with alcohol or other depressants. All opiates and opioids have a high potential for abuse and dependence, which increase with higher potency of the drug and more efficient routes of administration, such as injection or smoking. Injection practices also carry additional health risks from communicable diseases such as HIV/AIDS and hepatitis.

STIMULANTS

Stimulants such as amphetamines increase the activity of one or more of the monoamine neurotransmitters (dopamine, norepinephrine, and serotonin). Activation of the dopamine system is primarily responsible for the euphoric effects, or “rush,” of stimulants. Stimulants also enhance mood, promote wakefulness, increase respiration and blood pressure, and decrease appetite. Chronic abuse of stimulants can severely damage nerve cells and cause an array of psychiatric disturbances, including psychosis and paranoia, as well as motor disturbances, including tics.

Methamphetamine, sometimes known as “ice” or “crank,” is the product of a “street” modification of amphetamine using over-the-counter decongestants. It has an even greater stimulant effect on the dopamine system. In addition some of the precursor chemicals and solvents used to manufacture methamphetamine can be highly toxic and flammable, leading to serious safety risks from inhalation and potential explosions or fires. Methamphetamine can be taken orally, intranasally, intravenously, or by smoking. Abuse of methamphetamine has been associated with serious physical dependence and severe health consequences, including nervousness and agitation, tactile hallucinations, and paranoid psychosis, of which hallucinations and delusions may be refractory to treatment.

“Designer” stimulants such as “ecstasy” (methylene-dioxymethamphetamine, or MDMA) have potent effects on norepinephrine and serotonin in addition to dopamine. This elicits psychedelic or hallucinogenic reactions in addition to euphoria. Because norepinephrine affects the autonomic system, it can also precipitate rapid heart rate, increased blood pressure, and an elevated risk of cardiovascular events. MDMA intoxication enhances the pleasure of tactility, and users often seek physical contact with others. This may be observed at MDMA parties, or “raves,” where users may dance closely or aggressively with each other. Withdrawal from MDMA can precipitate disturbances in mood, insomnia, fatigue, and depression. Similar to methamphetamine, MDMA abuse can cause chronic damage to the brain.

Cocaine is a potent and highly addictive stimulant that can be snorted or injected. Cooking sodium bicarbonate (i.e., baking soda) with cocaine enables it to be smoked in the crystallized form of “crack,” which delivers a more potent yet shorter-lived high that may last only a few minutes. This rapid cycle of acute intoxication and withdrawal (or “crash”) has the potential to elicit sustained binge patterns and severe addiction to the drug. In addition to the health risks typically associated with stimulant abuse, the chemical properties of cocaine—such as its...
acidity and its typical intranasal method of delivery—can cause damage to nasal and sinus tissue.

DEPRESSANTS
Depressants represent a broad class of drugs that include anxiolytics, hypnotics, and sedatives. The most commonly abused depressant is alcohol. Benzodiazepines, which act on the inhibitory neurotransmitter GABA, are the second most commonly abused depressant and among the most commonly prescribed medications. Benzodiazepines prescribed for anxiety are called anxiolytics, while those prescribed for insomnia are called hypnotics. They have a wide therapeutic profile, covering the spectrum of sedation from minor tranquilizers to preoperative anesthetics. Acute side effects can range from mild memory loss to anterograde amnesia for new events occurring while intoxicated. The anterograde amnesia may be worsened when the drug is combined with alcohol. Few deaths have been attributed to benzodiazepine ingestion alone. It has been suggested that long-term use might cause permanent impairment of motor and cognitive functioning. But despite being in use for over forty years, its long-term effects are still uncertain.

Barbiturates are an older class of depressants that were prescribed similarly for anxiety and sedation. They were associated with serious side effects and had a relatively narrow therapeutic profile. Any mixture of barbiturates with alcohol has the potential to precipitate seizures, a severe withdrawal syndrome, or death. As a result their use has been almost totally usurped by benzodiazepines, and they are now prescribed only rarely for the treatment of convulsions or refractory migraine headaches.

HALLUCINOGENS
Most hallucinogens exist naturally in certain plants (e.g., mescaline and peyote). Others, such as LSD (lysergic acid diethylamide), are synthesized from ergot, a mold that grows on rye and other grains. Hallucinogens cause sensory or perceptual alterations that can be visual, auditory, tactile, olfactory (smell), or gustatory (taste). They can also cause thought disturbances, such as grandiose or paranoid thinking, and can lead to feelings of irrational pleasure or panic. Intense panic can lead to bizarre or dangerous behavior and have long-lasting psychiatric repercussions similar to those of post-traumatic stress disorder (PTSD). Hallucinogens act primarily on the serotonergic system, which, like MDMA, can elicit psychotic-like experiences.

Cannabis, or marijuana, is the most widely used illegal drug in the United States. Cannabis contains delta-9-tetrahydrocannabinol (THC), a psychoactive chemical that binds to naturally occurring cannabinoid receptors in several brain regions, including the hippocampus. The precise mechanism of action of THC is unclear. According to the FDA, cannabis has no legitimate medical usage; however, a synthetic analog of THC called dronabinol may be used medicinally as an appetite stimulant, to reduce nausea and pain, or to reduce intraocular pressure in glaucoma patients. Cannabis is typically smoked, but it can also be cooked and eaten with high-fat foods. Many users report feelings of euphoria, relaxation, and perceptions of heightened awareness, whereas others report mild to moderate levels of anxiety and paranoia. Long-term side effects of chronic use of cannabis may include reductions in sperm motility, increased estrogen levels, and decreased high-density (“good”) cholesterol. Although an “amotivational syndrome” characterized by impaired ambition and substandard productivity has been anecdotally attributed to long-term cannabis use, the existence of this syndrome has not been scientifically established. No deaths have been reliably attributed to cannabis ingestion, apart from vehicular or other accidents stemming from impaired judgment or motor coordination.

ANABOLIC STEROIDS
Anabolic-androgenic steroids (AAS) are synthetic forms of the primary male sex hormone, testosterone. The major consumers of illegally obtained AAS are bodybuilders and athletes, who seek their anabolic properties for athletic or aesthetic gains while also attempting to minimize their androgenic properties, which elicit most of the unwanted side effects. The dangers of AAS are clearly documented, even when they are used according to prescription standards. Documented adverse physical risks include permanent liver injury, increased blood pressure and risk of stroke, acne, hair loss, and sudden cardiac death. Males may experience testicular atrophy and the development of female sex characteristics such as breast enlargement. Female users may develop masculine characteristics such as facial hair and voice deepening as well as menstrual irregularities and clitoral enlargement. The psychiatric effects of AAS abuse can be unpredictable and range from elevated mood to sudden and irrational aggressiveness. Upon cessation of AAS, particularly after sustained high doses, users may experience depression and withdrawal, lowered energy, decreased libido, and a precipitous loss of muscle mass. All AAS carry a risk of physical and psychological dependence.

INHALANTS
Inhalant abuse, or “huffing,” involves the deliberate intake of fumes from solvents (e.g., paint thinner) or aerosol gases used as propellants (called “whippets”). Inhalant intoxication may appear similar to alcohol intoxication, but the subjective effects are reported to be more anesthetic than those of alcohol. Solvent inhalants are cor-
rosive to tissue and extremely dangerous to inhale in concentrated forms. All huffing temporarily deprives the brain of oxygen, and anoxia is a risk to all inhalant abusers. Inhalant abuse can cause severe adverse health effects, including damage to the heart, lungs, liver, and kidneys. Inhalant abuse can also lead to acute amnesia, stroke, coma, and death.

LAW ENFORCEMENT EFFORTS

In the United States the Drug Enforcement Administration (DEA) "schedules" drugs according to whether they have (1) a legitimate medical usage and (2) a potential liability for abuse or dependence. Similar scheduling mechanisms are employed by many other countries as well. If the U.S. Food and Drug Administration (FDA) determines that a drug of abuse has no legitimate medical usage, then it is classified as Schedule I by the DEA. Drugs with legitimate medical uses are classified into Schedules II through IV, depending on their abuse potential (see table 2). The schedule has important implications for prescription practices, including permissible refills and the need for handwritten, as opposed to verbal, prescription orders. Issues of toxicity and side-effect profiles do not influence scheduling by the DEA, but they do influence the FDA's approval of medications for specific conditions, based upon a balancing of each medication's risks versus benefits.

Tobacco and alcohol each have a moderate to high abuse potential and no legitimate medical usage (not to mention high mortality and morbidity risks), yet they are neither regulated by the FDA nor scheduled by the DEA. Instead, largely for policy reasons, they are regulated by the U.S. Bureau of Alcohol, Tobacco, and Firearms (ATF) with regard to such matters as licensing and regulation of sales.

DEMOGRAPHIC USE PATTERNS

In 2005 rates of substance abuse or dependence in the United States varied to some degree by racial or ethnic group. However, they did not vary across the most populous demographics of Caucasians, African Americans, and Hispanics (see table below).

Despite similar use-prevalence patterns, Hispanics in the United States are imprisoned at more than twice the rate of Caucasians for drug-related offenses, while African Americans are imprisoned at 1.8 times the rate. The disparity is even more pronounced for Hispanics who are imprisoned at 2.9 times the rate of Caucasians.
Americans are imprisoned at nearly four times the rate of Caucasians (Bureau of Justice Statistics 2006). These apparent discrepancies might be attributable to differential law enforcement practices. For instance, police might focus greater attention on minority communities, or prosecutors might offer minority defendants fewer opportunities for plea bargains or diversionary programs. In addition sentencing guidelines could contribute to unintended disparate impacts on minority groups. For example, there is some indication that crack-cocaine may be used relatively more frequently among African American individuals in urban environments, whereas methamphetamine may be used more frequently among Caucasians in rural environments. Higher penalties can attach in the United States to the crack form of cocaine, as compared to its powder form, and this might account in part for higher incarceration rates among African Americans. With newer laws being enacted to stem the rising tide of methamphetamine abuse, changes might also be seen in demographic patterns among arrestees and inmates. More research is required to gain a better understanding of this important issue and to plan for effective corrective actions.

DUAL ECONOMY

In the mid-twentieth century, theoretical modeling of economic growth was dominated by single-sector models, such as that of the Nobel Prize winner Robert Solow. Other analysts, however, felt that economies should be characterized as having multiple sectors, which they stylized into dual-economy models. Foremost among the early dual-economy modelers were two other Nobel Prize winners, W. Arthur Lewis and Simon Kuznets. The dual economy models posited an economically “advanced” sector and an economically “backward” sector. These have alternatively been called capitalist and subsistence, formal and informal, modern and traditional, industry and agriculture, urban and rural, primary and secondary, and good-jobs and bad-jobs sectors.

For both Lewis and Kuznets, the two sectors differed in terms of the goods produced, the nature of the growth process, and conditions in labor markets. Lewis specified a capitalist sector that produced industrial goods and a subsistence sector that produced agricultural goods, services, and commercial activities. Kuznets distinguished an agricultural sector from all others, primarily the industrial sector. For Lewis, capital accumulation took place in the capitalist sector only, and he viewed this sector as the engine of growth. For Kuznets, the essence of modern economic growth was the gradual shift of production from lower-income to higher-income sectors. For both Lewis and Kuznets, the advanced sector offered higher real wages than the backward sector did.

This coexistence of high-wage and low-wage sectors is the defining feature of labor-market dualism, the generalization of which is labor market segmentation. Besides real wages being higher in the good–jobs sector, dualism and segmentation require that access to this sector be restricted, in the sense that not all who want to work there are able to do so. As summarized by Michael Wachter, the dual labor-market model advances four hypotheses:

First, it is useful to dichotomize the economy into a primary and a secondary sector. Second, the wage and employment mechanisms in the secondary sector are distinct from those in the primary sector. Third, economic mobility between these two sectors is sharply limited, and hence workers in the secondary sector are essentially trapped there. Finally, the secondary sector is marked by pervasive underemployment because workers who could be trained for skilled jobs at no more than the usual cost are confined to unskilled jobs. (1974, p. 639)

Some of the subsequent writings on labor-market dualism adopted human capital theory, as developed in the Nobel Prize–winning work of T. W. Schultz and Gary Becker and the work of Jacob Mincer. Human capital the-
ory maintains that workers with more education and training have higher skills, which the labor market rewards. Thus, it is not enough for labor-market dualism that workers in one sector earn systematically more than those in another; it must also be true that workers with the same skills do better in one sector than in another. Ample research has demonstrated empirical evidence that wages are systematically higher for observationally equivalent workers in some economic sectors than in others: non-agriculture versus agriculture, urban versus rural, formal versus informal, and so on. Many observers take this as evidence of labor-market dualism, though some dismiss it as merely indicating the existence of unmeasured skills and abilities.

What the works reviewed thus far have in common is that all available workers are employed either in the advanced sector or in the backward sector. Thus, unemployment is absent in these models. Later models, such as that of John Harris and Michael Todaro, specified two types of employment (industrial and agricultural) plus unemployment.

One feature that could not be ignored by labor market modelers was the duality within the urban economy, with some jobs being desirable and others being deemed quite miserable to have. This observation led to the development of a model with three types of employment: an urban formal sector, an urban informal sector, and a rural agricultural sector—plus unemployment. More recently, one more need has become apparent. This is to give due recognition to the fundamental duality to be found within the informal sector. On the one hand, the informal sector has free-entry activities such as street vending and small-scale services that enable those who do such work to eke out a meager existence. Individuals who engage in such enterprises do so because it is better for them than being unemployed. On the other hand, the informal sector also has restricted-entry activities that people who could be working formally choose to take up instead, such as leaving a formal sector auto repair shop to set up one’s own backyard operation or moving from a formal sector restaurant to operate one’s own noodle stand. Some current segmented labor-market models include both the “free entry” part of the informal sector and the “upper tier” of the informal sector.

In the 2000s, dual-economy and multisector models dominate both academic research and applied policy work. Analysts routinely utilize models with many economic sectors and many labor markets. The sectors, at a minimum, include industry and agriculture, while other sectors, such as commerce and services, may also play a role. As for the labor market, workers might be employed (be it in wage employment or self-employment) in one of four sectors: the formal sector, the free-entry part of the urban informal sector, the upper tier of the urban informal sector, and rural agriculture. They might also be unemployed. Models assuming that the economy has only a single sector or that all employed workers earn the same amount seem hopelessly unrealistic.

DUALISM

DU BOIS, W. E. B. 1868–1963

William Edward Burghardt Du Bois was a leading public intellectual whose extensive body of research, social analysis, and cultural critique helped to establish the foundations for the social sciences, the study of race relations, and Africana studies in the United States. Widely recognized as a historian and sociologist, he also engaged anthropological discourse on race during the era of Franz Boas (1858–1942) (Baker 1998; Harrison 1992). His influence on African American anthropologists W. Allison Davis (1902–1983), St. Clair Drake (1911–1990), and Irene Diggs (1906–1998), who studied with both him...
Du Bois, W. E. B.

and Fernando Ortiz (1881–1969), is particularly significant. Beyond his work in the social sciences, his immense interdisciplinary breadth encompassed autobiography, philosophy, journalism, and creative writing. In his two earliest novels, *The Quest of the Silver Fleece* (1911) and *Dark Princess: A Romance* (1928), he explored important political and economic themes, situating them in the context of romance and dramatic psychosocial plots featuring female protagonists in complex settings. Novels represented one of the many genres in which Du Bois expressed his evolving vision of the possibilities of antiracist and anticolonial agency.

Du Bois was born on February 23, 1868, in Great Barrington, Massachusetts. In 1884 he graduated as the valedictorian of his high school class. In 1885 he went to Nashville, Tennessee, to attend the historically black Fisk College (now University). During his summers in Tennessee, he taught in segregated rural schools. That experience gave him a close look at the poverty and racial discrimination that African Americans faced in the South. It also exposed him to their dynamically expressive cultural life. Memories from that period inspired some of his later writings, namely, *The Souls of Black Folk* (1903). After three years, he graduated from Fisk with a BA. With a scholarship, he continued his studies at Harvard, where he was classified as a junior because of the presumed inferiority of his education at Fisk. He studied with philosophers William James (1842–1910) and George Santayana (1863–1952), and with economist Frank William Taussig (1859–1940), completing his bachelor's degree in philosophy cum laude in 1890. He remained at Harvard for graduate training in history and political science, earning his MA and PhD in 1891 and 1895, respectively. Historian Albert Bushnell Hart (1854–1943) encouraged his research on the transatlantic slave trade.

Financed by a Slater Fund Fellowship, Du Bois spent 1892 to 1894 at the Friedrich-Wilhelm III Universität at Berlin, known also as the University of Berlin, where he concentrated in history and political economy, and developed a scientific approach to the study of social problems. He took courses from political theorist Rudolph von Gneist (1816–1895) and economist Adolph Wagner (1835–1917). He also attended lectures by Max Weber (1864–1920), whose temporary lectureship at Berlin coincided with Du Bois’s second year there. The most significant aspect of his graduate studies in Germany was his training in economics and sociology under the tutelage of Gustav von Schmoller (1838–1917), the leader of the “younger German historical school” that revealed economics’ interrelations with the other social sciences. This school of thought also questioned theories of universal laws, emphasizing that economic behaviors were contingent upon historical, social, and cultural contexts. Schmoller’s methodology valorized the use of induction to accumulate historical and descriptive facts. In his view, “the goal of social science was the systematic, causal explanation of social phenomena” (Green and Driver 1978, p. 6). He also believed that methodologically rigorous social scientific research “could be used as a guide to formulate social policy” (p. 6). This empirical approach strongly influenced Du Bois’s early career as a social scientist who applied sociological techniques to study the problems presented by “the color line.”

Du Bois’s experiences in Europe expanded his thinking considerably. He realized that the racial discrimination he had encountered in the United States was not universal and that racism’s scope was larger than the problems in the United States. American racism, colonial oppression in Africa and Asia, and Europe’s political-economic development were all components of the same set of interrelated problems. Du Bois also gained greater exposure to Marxism and socialist analysis from attending meetings of the Social Democratic Party. The maturation of thinking that began to emerge in Germany was reflected many years later in *Color and Democracy: Colonies and Peace* (1945) and, even before that, in *Black Reconstruction* (1935). In the latter book, he innovatively used Marxist categories and “anticipated” Gramscian and poststructural approaches to hegemony and discourse in his analysis of the socioeconomic, political, and ideological conditions that prevailed in the U.S. South after the Civil War (1861–1865) (Nonini 1992). Contrary to the Dunning school’s notion that freed blacks were incapable of exercising the rights of citizenship, Du Bois posited that African Americans played a major role in building democracy after emancipation. He further argued that the racism and ambivalent allegiance of poor whites to the white elite could be attributed to a public psychological wage. These ideas were controversial but seminal in influencing later generations of scholars, such as those who study the social construction of whiteness (e.g., Roediger 1991).

Although he intended to complete his doctorate in economics in Germany, Du Bois had to return to the United States. Despite Schmoller’s and Wagner’s strong support for his exemption from the doctoral program’s four-semester rule, a professor of chemistry was adamant against it. However, even more of an obstacle was the paternalistic Slater Fund. It refused to renew his fellowship for only one more semester because of the higher priority it gave to channeling African Americans into elementary and industrial education. Du Bois was urged to “devote [his] talent and learning to the good of the colored race” (Lewis 1993, p. 146). A comparative study of the household economies and quality of life among German peasants and rural African Americans in Tennessee was not viewed as a suitable goal for an educated black person.
The following year, while teaching at the African Methodist Episcopal Church–affiliated Wilberforce University in Ohio, he earned his PhD from Harvard's Department of History and Government, becoming the first African American to earn a doctorate from that university. His dissertation, The Suppression of the African Slave Trade to the United States of America, 1638–1870, was published as the first volume in the Harvard Historical Studies series (1896). Representing a “new historiography of interpretation,” the dissertation provided thorough documentation for the argument that due to “an interregional bargain [between the North and South] sealed by profits,” the United States continued to participate in the slave trade after it was internationally abolished in 1807 to 1808 (Lewis 1993, pp. 156, 160). Despite federal and state laws codifying suppression, a clandestine nonenforcement persisted for half a century.

In 1896 Du Bois assumed a temporary position as “assistant instructor” at the University of Pennsylvania, which created a position beneath its lowest rank to accommodate hiring a Negro. Du Bois’s charge was to conduct research on the cause of urban problems in the predominantly African American seventh ward of Philadelphia. The city’s “reforming elites” had commissioned the research, which Du Bois conducted over fifteen months, collecting survey and demographic data, and conducting interviews with five thousand people (Lewis 1993, p. 180). The result was The Philadelphia Negro: A Social Study (1899), an exemplary treatise that was the first large-scale empirical study in U.S. sociology and the first scientific investigation of African Americans (Green and Driver 1978, p. 113; Lester 1971, p. 26). Given many of the project’s substantive concerns as well as the centrality of participant observation, The Philadelphia Negro may also be placed in the context of the history of urban anthropology (Harrison 1992). In a social and intellectual climate dominated by social Darwinism, Du Bois’s analysis demonstrated that the problems of poverty and crime were not caused by innate black inferiority. They were instead symptoms of institutionalized racial inequality. Although his empirical results challenged conventional thinking, his elitist disposition, nonetheless, led him to play into the moralizing judgments of his patrons. Despite the intellectual and public policy significance of this research, Du Bois was not retained in either a temporary or permanent position at the University of Pennsylvania, where white classmates of lower rank became full professors (Du Bois 1968, p. 199).

After Philadelphia, Atlanta University appointed Du Bois professor of economics and history with the responsibility of directing the Sociological Laboratory and the Atlanta University Conference. The latter was a series of annual conferences to report the results of the laboratory’s research on the impact of urban problems on black Americans. The emphasis, especially during the earlier years, was on the collection of factual evidence on social conditions rather than on social reform, which was believed to be possible only after ignorance was countered by knowledge. The goal of the research was the “careful search for truth” that would offer an empirical alternative to the speculative theories and “vindictive ignorance” of much of the social science of that time (Green and Driver 1978, p. 14). Du Bois published the results of this research program in the monograph series that made up the Atlanta University Publications (1896–1914). The studies addressed a wide range of issues: health and physique, housing, black businesses, education, artisans, the black church, crime, economic cooperation, the family, morals, and manners. In Health and Physique of the Negro American (1906), for example, Du Bois offered a critique of early physical anthropology’s biological determinism and scientific racism. Using craniometric and public health data, he documented the adverse effects of social conditions on the black body.

Du Bois’s tenure at Atlanta University ended in 1910 when he shifted his focus from that of a detached social scientist to an activist, following “the path of sociology as an inseparable part of social reform” (Green and Driver 1978, p. 20). Convinced at this point that knowledge and truth were insufficient for promoting social change, he became editor of the newly established NAACP’s magazine, The Crisis. This transition into the life of an activist intellectual followed his antiracist activism of three years earlier in cofounding the Niagara Movement, which had a short life. Du Bois served as Crisis editor until 1934, when friction over his editorial independence from the NAACP’s executive secretary, Walter F. White (1893–1955), and board led him to resign. During the twenty-four years of his editorship, he became the most influential black public intellectual in the United States, educating the public on the plight of African Americans and others in the African world, articulating a vision for civil and human rights and black empowerment (one that was often more radical than that of the NAACP), and providing an outlet for talented young writers and scholars.

A prolific scholar, Du Bois published across a wide interdisciplinary terrain. His most widely read book was The Souls of Black Folk, a collection of essays, some autobiographical, written in a compellingly lyrical, poetic style. Positioning that the color line was the problem of the twentieth century, the book redefined the meanings of black identity and lived experience, illuminating the dilemmas of double consciousness as well as the enhanced social vision that could potentially emerge from it. The book also offered a poignant view of the South, including an examination of everyday life in the Black Belt and the limits of Booker T. Washington’s (1856–1915) accommodationist stance. Souls is also invaluable for its “pioneering
excursion into the sociology of music” (Lewis 1993, p. 286), religion, education, and politics.

In 1934 Du Bois began his second tenure at Atlanta University, serving as head of the Department of Economics and Sociology. During this phase, he focused his scholarship on comparison and synthesis informed by his commitment to social action and politicization within an international context. Among his publications were Black Reconstruction (1935) and Black Folk Then and Now: An Essay in the History and Sociology of the Negro Race (1939)—an expansion of The Negro (1915). He also started to work on the Encyclopedia Africana, which he had initially envisioned early in the century. He established Phylon, a journal devoted to critical studies of race and culture, and in the early 1940s he worked to revive the Atlanta University Conference. The conference held in 1943 featured a number of prominent black and white sociologists, including E. Franklin Frazier (1894–1962), Charles S. Johnson (1893–1956), Howard W. Odum (1884–1954), and Edgar T. Thompson (1900–1989).

Despite his success, the university administration, wary of his radicalism, forced Du Bois to retire. He accepted an offer from the NAACP to serve as its director of special research, a position he held for only four years. He sought to revitalize the Pan-Africanist movement, help define international human rights standards for the newly established United Nations, and examine the global scope of racism. His radical anticolonial views, however, were not consistent with the NAACP’s policies. After his second tenure with the NAACP, Du Bois went on to leadership positions with the Council on African Affairs and the Peace Information Center, which led him to become involved in controversial international affairs related to the cold war. His participation in the leftist peace movement and his travels to the Soviet Union and China during the 1940s and 1950s were viewed as “un-American” as McCarthyist anticommunism held sway. In 1951 Du Bois was indicted on charges of being an unregistered agent of a foreign principal. Although acquitted of the crime, the prosecution stigmatized Du Bois, alienating him even further from the mainstream civil rights leadership.

Du Bois devoted much of his life to building international networks and deepening anticolonial convictions among activist intellectuals from Africa and the African diaspora. He organized a series of Pan-African Congresses over the first half of the twentieth century. In the last years of his life, he accepted an invitation from Prime Minister Kwame Nkrumah (1909–1972) to work on the Encyclopedia Africana with support from the government of postcolonial Ghana. Du Bois moved to Accra and became a Ghanaian citizen. His encyclopedia unfinished, he died on August 27, 1963, the day before the historic March on Washington.

**DUE PROCESS**

The term *due process* refers to the guaranteed rights that ensure that an individual cannot be deprived of “life, liberty, or property, without due process of law.” This provision, as it applies to the U.S. federal government, is found in the Fifth Amendment to the U.S. Constitution. It is also found in the Fourteenth Amendment, where it constrains the actions of the states. The notion of due process arises from the premise that law should be fair, predictable, and transparent. Perhaps more importantly, a guarantee of due process ensures that whenever the sovereign or government interacts with an individual, it is bound by the law from both a substantive and procedural perspective.

The Bill of Rights (the first ten amendments to the U.S. Constitution) initially only acted as a constraint on the actions of the federal or national government. Once the Fourteenth Amendment was enacted after the Civil War, the U.S. Supreme Court utilized the due process clause to incrementally apply those constraints to the state governments. Through the process known as “incorporation,” the due process clause served as the conduit to apply the Bill of Rights to the relationship between individuals and the state governments.

The Court did not apply all the governmental restrictions of the Bill of Rights at once, however. Rather, over time, the Court incorporated more discreet rights using a progressively broader configuration of the due process clause. For instance, in *Mapp v. Ohio* (1961), the Court ruled that the Fourth Amendment prohibited states from introducing illegally obtained evidence during criminal prosecutions. This “exclusionary rule”—which holds that improperly obtained evidence must be excluded from the prosecution’s case—supported and gave weight to a line of previous cases that prohibited unreasonable searches and dictated the need for “probable cause” before a search warrant could be issued. The Fifth Amendment prohibitions on double jeopardy or compelled self-incriminating testimony were also held to apply to state actions. In *Miranda v. Arizona* (1966), the Court determined that the right to an attorney contained in the Sixth Amendment and the right against self-incrimination contained in the Fifth Amendment were so important that the police must affirmatively advise suspects of those rights before questioning a detained suspect.

The notion of due process is not limited by the text of the Bill of Rights. Although the Court has incorporated many specific provisions of the rights contained in the Constitution, it has embraced a broader notion of due process that suggests an independent constraint on governmental procedures that are not particularly derived from constitutional text apart from the due process clauses. For instance, in *Rochin v. California* (1952) the Court held that shocking behavior can violate procedural due process even if no specific text of the Constitution is at issue (in this case, the police forcibly pumped out a suspect’s stomach to recover drugs he had swallowed upon their entry). Fundamental notions of decency and fair process are thus intrinsic aspects of due process.

Although most questions about due process are concerned with procedural due process—the process or procedure at issue—on occasion the Court has considered substantive aspects of due process. In *Skinner v. Oklahoma* (1942), the Court used a substantive due process analysis as the basis for overturning a criminal statute in Oklahoma that provided for the sterilization of some three-time felony offenders but not others. There is a debate as to whether the right to privacy found in the emanations and penumbras of the Bill of Rights, as found in *Griswold v. Connecticut* (1965) and *Roe v. Wade* (1973) is grounded in substantive due process. In *Griswold* the Court found that a right to privacy prohibited Connecticut from outlawing birth control for married couples, and in *Roe* the Court recognized the right of women to obtain an abortion before the third trimester of pregnancy.

The foundational expectation of due process means that government bodies, agencies, and actors must provide some set review before depriving an individual of life, liberty, or property, broadly defined. The required process may take the form of administrative hearings, appellate procedures, or some other forum to hear and oppose the prospective governmental action. Since the time of the Magna Carta in England, due process has meant a fundamental demand that the government follow the appropriate law. The concept, as well as the fundamental transparency and fairness it implies, holds in both international legal regimes and any constitutionally grounded government.

Product dumping is selling exports at a price that is less than “normal value.” The traditional definition of dumping is selling exports to buyers in a foreign country at a price that is less than the price that is charged to comparable domestic buyers (or to buyers in other foreign-country markets). A second, alternative definition, adopted starting in the 1970s, is selling exports to buyers in a foreign country at a price that is less than the average cost of producing the product (including allocation of fixed costs and profit).

Why would an exporting firm be dumping (according to one or the other of these definitions)? There are different reasons. A firm may be engaged in predatory dumping, planning to drive out other competitors and then raise its price once it has achieved monopoly power. A decline in market demand can drive the market price to a level that is below full average cost. A firm with substantial production or inventory of a product that is perishable or going out of fashion may optimally set a price that is below its full average cost. A firm may be introducing its product into a new foreign market, and to encourage initial sales it may set a low price. A firm with market power may be using geographic price discrimination, charging a higher price in its home market (where the price elasticity of demand is lower) and a lower price in the foreign market (where the demand elasticity is higher).

The rules of the World Trade Organization permit the importing country’s government to impose an antidumping duty if the government follows a process that finds that dumping is occurring and that the dumping is causing injury to domestic import-competing firms. The antidumping duty is intended to force the price of the imported product back up to its normal value.

For the well-being of the importing country (and the world overall), the process of imposing antidumping duties has two major shortcomings. First, the process does not require the government to consider possible benefits to other groups in the country (for instance, domestic consumers of low-priced imports). Second, the process is subject to political manipulation and bias. Import-competing producers can exert substantial pressure for favorable rulings. There is leeway in how a government body makes comparisons of prices in different national markets or measures full average costs of foreign producers. For instance, the U.S. Department of Commerce finds that dumping has occurred in more than 90 percent of the cases that it examines. But Brink Lindsey and Dan Ikenson (2002) examined a sample of cases in depth and concluded that in over half of them there was no dumping or much less than the Department of Commerce had determined. It appears that antidumping policy often is used not to combat unfair exporting policies that harm the importing country, but rather to provide new protection for domestic firms against competitive imports, with the typical inefficiency losses to national (and world) well-being.

Up to the late 1980s, only three countries (the United States, Canada, and Australia) and the European Union actively used antidumping policies. Since then, more countries have adopted antidumping laws (at least ninety-five countries as of 2005). According to data compiled by the World Trade Organization, the importing countries that initiated the most cases during the 2000–2006 period are India, the United States, China, Argentina, and Turkey, as well as the European Union. During this period, China is the exporting country whose firms were most often found to be dumping. Other exporting countries whose firms were often found to be dumping include Korea, Taiwan, Japan, and the United States.

century. His key scholarly contributions include the introduction of path analysis to sociology, the measurement of occupational socioeconomic standing with an index (Duncan Socioeconomic Index), the study of intergenerational occupational mobility, the spatial analysis of residential patterns, the application and advancement of loglinear models and Rasch models for categorical social science data, and a landmark treatise on social measurement (Duncan 1984).

Duncan's best-known work is a 1967 book coauthored with the late Peter Blau, *The American Occupational Structure*. Based on quantitative analyses of the first large national survey of social mobility in the United States, the book elegantly depicts the process by which parents transmit their social standing to their children, particularly through affecting the children’s education. The book’s impact went far beyond its analyses of occupational mobility. Using survey data and statistical techniques, it showed how an important sociological topic could be analyzed effectively and rigorously with appropriate quantitative methods. The work helped inspire a new generation of sociologists to follow suit and pursue quantitative sociology. Today, a worldwide community of sociologists studying the transmission of social standing from one generation to the next still works on elaborating the Blau-Duncan model to include such additional factors as cognitive ability, race, and social context.

Duncan introduced path analysis to social science. A path diagram and a corresponding path model describe a set of equations summarizing complex scientific ideas in terms of statistical relationships. Path analysis was first invented by Sewell Wright, a biologist and evolutionary theorist. Duncan discovered Wright’s method of path analysis by chance and then applied it to sociology. Together with Arthur Goldberger, an econometrician, he showed that path analysis models were closely related to the simultaneous equation models of economics and the confirmatory factor analysis of psychology. These three different ways of analyzing certain kinds of data can be viewed within a single general framework called *structural equation models*. Later in his career, Duncan concentrated his methodological interests on loglinear models and Rasch models for categorical data.

In his last book, *Notes on Social Measurement, Historical and Critical* (1984), Duncan shifted his attention to social measurement and presented his general philosophy of social science. Tracing the historical development of social measurement from Ancient Greece to the present, Duncan identified the difficulties of quantitative analyses in the social sciences, in which variability is the norm rather than the exception. Partly in response to his own critics, Duncan also presented himself as a fierce critic of aspects of the quantitative approach—something that he had helped launch as a new standard for social science. This change in Duncan’s methodological thinking can be traced to his realization that population heterogeneity renders statistical analyses of social science data essentially descriptive rather than causal. Indeed, avoidance of drawing law-like causal statements from statistical analyses became the hallmark of the intellectual tradition in quantitative sociology that is associated with Duncan. He was openly disdainful of the search for supposedly universal laws of society that would mimic those of physical science. The central tenet in Duncan’s new paradigm for quantitative sociology is the primacy of empirical reality.

Duncan was born on December 2, 1921, in Nocona, Texas, and grew up in Stillwater, Oklahoma. He completed a BA at Louisiana State University in 1941, and an MA at the University of Minnesota in 1942. He then served three years in the U.S. Army during World War II (1939–1945) before completing his PhD in sociology at the University of Chicago in 1949. He was on the faculty in the departments of sociology at Pennsylvania State University, the University of Wisconsin, the University of Chicago, the University of Michigan, the University of Arizona, and the University of California, Santa Barbara, from which he retired in 1987.

Duncan was elected to membership in the National Academy of Sciences, the American Academy of Arts and Sciences, and the American Philosophical Society. He was also awarded honorary degrees by the University of Chicago, the University of Wisconsin, and the University of Arizona. He was president of the Population Association of America from 1968 to 1969.

DURATION MODELS

*Duration models* are used to describe the amount of time that elapses until a given event, or the length of time spent in a given state. Duration models have been used to examine many phenomena, including labor-market outcomes,
Duration Models

by modeling the length of time spent in unemployment; industry consolidation, by modeling time elapsed until a firm is acquired by another firm; criminal recidivism, by modeling time elapsed until conviction for a criminal offense for persons released from prison; and the viability of medical procedures, by modeling time until death, relapse, or recurrence after surgery.

Duration models share a duality relationship with count-data models. In count-data models, one models the number of occurrences of some event within a specified interval of time. If, for example, counts of some event are distributed Poisson, then the intervals between events can be shown to have an exponential distribution. One can model either counts over a time interval, or the intervals between the events comprising the counts. Duration models are often used in situations where only one interval is observed for each agent, as in the case of unemployment spells or the lives of firms.

In many cases, data on durations are censored. Suppose one collects data on durations in a given state by conducting surveys at calendar times \( t_A \) and \( t_B \). Figure 1 illustrates four possibilities. At time \( t_A \), agent 1 has not yet entered the state of interest, but by time \( t_B \), he has entered and exited the state at times between \( t_A \) and \( t_B \). Hence if the survey at time \( t_B \) asks the right questions, it will be possible for the researcher to observe this agent’s time in the spell completely. Agent 2 enters the state of interest prior to the time of the first survey, and exits prior to the time of the second survey; again, if the right questions are asked, it will be possible for the researcher to observe this agent’s complete duration as well. In some cases, however, depending on how the first survey is conducted, agent 2’s time of entry into the state may be unobserved, in which case this agent’s duration will be left-censored; all the researcher would know in this case is that the agent was already in the state of interest at time \( t_A \), and the time of exit before time \( t_B \). Agents 3 and 4 remain in the given state until after the time of the second survey; for these agents, the researcher can know only that they remained in the state of interest at time \( t_B \) and were still waiting to exit. Observations for these agents are right-censored; in addition, if the entry time for agent 3 is unknown, the observation for this agent will be both left- and right-censored.

The maximum likelihood method is often used to estimate duration models after specifying a distribution function

\[
F(t) = \Pr(T \leq t)
\]

for the random variable \( T \) describing the length of time spent in a state. Because durations are necessarily non-negative, one must specify a one-sided distribution for \( T \); examples include the exponential, Weibull, Gompertz, and log-normal distributions. The distribution function

\[
F(t) \text{ implies a density function } f(t) = dF(t), \text{ a survivor function } S(t) = 1 - F(t) \text{ which gives the probability of remaining in the state up to time } t, \text{ and a hazard function }
\]

\[
\lambda(t) = f(t)/S(t) = \lim_{h \to 0} \frac{\Pr(t \leq T < t + h | T \geq t)}{h}
\]

giving the rate at which exits occur at time \( t \). The goal of researchers is often to estimate the marginal effects of various covariates on the hazard rate.

John Kalbfleisch and Ross Prentice (2002), Tony Lancaster (1990), and Colin Cameron and Pravin Trivedi (2005) give extensive details on specification, censoring in, and estimation of duration models, as well as examples of applications.

Paul W. Wilson
Émilie Durkheim, the son of a rabbi from Eastern France, has long been recognized as a founding figure in modern sociology following his attempt to establish the subject as a respected scientific discipline in the academic world. Durkheim defined the subject matter of sociology as separate not only from that of natural sciences such as biology but also from other social sciences such as psychology and economics, which also studied the activities of the individual as a member of a group. Durkheim's seminal contribution to the establishment of sociology centered upon his founding of the journal *L'Année sociologique* in 1896, which addressed a whole range of issues including the economy, crime, law, and punishment. Journal entries on these and other topics allowed Durkheim to have an important influence in sociology and other social science disciplines.

Durkheim also advanced knowledge of the ideas of society, morality, and religion. One claim open to debate is that Durkheim was a social realist. This led him to challenge the assumption made by earlier Enlightenment philosophers that society was only a subjective and artificial entity because it was not part of nature. Instead, Durkheim argued that one should see society as an objective or observable reality that could be studied scientifically using empirical methods. To become scientific, sociology must study *social facts*. In *Rules of Sociological Method* (1895) Durkheim defined social facts as those emergent properties and realities of a collectivity which could not be reduced to the actions and motives of individuals, and that individuals were shaped and constrained by their external social environments. It was because social facts existed in their own right independently of individuals that Durkheim viewed society as a *sui generis* reality, which was subject to processes that could be understood only with reference to other social forces. Examples of social facts include language, religion, the economy, and law. These facts were real and should be studied as things. This meant that social phenomena could be known through observation which in turn made them capable of being analyzed as rigorously as objects or events in nature. Durkheim's conceptualization of society was nevertheless criticized for being ambiguous. In *Émile Durkheim: His Life and Work* (1973) Steven Lukes noted that Durkheim used the term *society* in various senses to mean the association of individuals, cultural transmission, socially prescribed obligations, system of rules, symbolic representations, or a national entity such as "French society." In 1894 Gabriel Tarde challenged Durkheim's notion of social facts, suggesting that they could not exist in their own right independently of individuals because social phenomena were transmitted from individual to individual.

Closely linked to the idea of society was Durkheim's original theory of morality. Here the obligation to act in accordance with moral rules came from society not nature, as earlier Enlightenment philosophers had supposed. Durkheim consequently saw morality as a collective social fact. Rules of moral conduct existed outside individuals and transcended personal likes and dislikes by being directed towards others in line with society's ideals and values concerning the common good. Observable laws and sanctions were imposed by society to prevent deviations from its moral rules. The scholar J. M. A. Darlu nevertheless objected, arguing in 1906 that Durkheim's interpretation of morality prevented him from addressing the individual's capacity for reason and their scope for rebellion against an existing set of collectively agreed moral rules. Furthermore, other scholars often allege that Durkheim's theory of morality—and indeed his sociology more generally—led him to ignore the phenomenon of social conflict. Marxist critics such as Tom Bottomore build upon this point when arguing that Durkheim placed an exaggerated emphasis on social order at the expense of paying adequate attention to social change. Anthony Giddens challenged the validity of this criticism when noting Durkheim's deep concern with the turmoil affecting European societies in his own day. This concern was expressed through Durkheim's conceptualization of the interests of the individual in conflict with those of society as a whole.

Durkheim's understanding of society and morality were inextricably bound up with his sociological theory of religion, which advanced knowledge by challenging the ideas of traditional theology. In *The Elementary Forms of Religious Life* (1912), Durkheim saw religion as the source of everything social. Central to Durkheim's definition of religion was the idea of the *sacred*. Sacred objects included symbolic things as diverse as a cross, flags, owls, or stones, all of which could be seen as extraordinary and set apart from the ordinary or *profane* things in everyday life. Beliefs and practices such as religious rituals also existed in relation to sacred things. Beliefs and practices generated the idea of moral community which in turn brought us back to the idea of sacred things. The sacred, beliefs and practices, and moral community, as the three basic elements of religion, were important because they bound individuals to the social group. Theological ideas about God and the supernatural were, however, missing from Durkheim's definition of religion. Religion was not simply an individual's communion with God. It was above all a form of collective life, and a way for the faithful, in their relationships with the sacred, to understand their connections with one another in society.

Durkheim's theory of religion has been criticized on a number of grounds. W. D. Wallis argued that religion was not essentially social and that the sociological viewpoint...
was only one among many. Contrary to Durkheim's own view, it was necessary to include the concept of the supernatural into a definition of religion. In the 1990s critics such as Fernando Uricoechea claimed that Durkheim took the idea of the sacred for granted and did not account for its genesis or source. Stjepan Meštrović further suggested that there has been a failure in contemporary Western societies to renew shared moral values. This has led agreement about what is sacred to become splintered into a myriad of competing meanings. This last criticism nevertheless overstates the diminution of the sacred. Meštrović's criticism, argued Jonathan Fish, was weakened through its failure to engage with Durkheim's important insights on the recurrent nature of sacralizing and resacralizing tendencies as an enduring feature of social life.

Durkheim's status as a founder of modern sociology was also linked up with his original theories of the division of labor, collective consciousness, and anomie in modern Western society. As societies industrialized, urbanized, and became more complex, specialized institutions concerned with government, industry, business, and education arose each with their own particular functions. A complex division of labor based on occupational specialization, diversification, and cooperation accompanied the emergence of these specialized institutions where people performed different work activities or occupational roles in society in line with their respective talents. Durkheim advanced sociological knowledge by rejecting the French philosopher Auguste Comte's earlier view of the division of labor. Instead of seeing this division as a negative force which eroded the sense of community between people, Durkheim viewed it in more positive terms as a potential source of social cohesion capable of binding individuals together through the performance of their specialized and yet interdependent work roles.

It was through the performance of these interconnected work roles that human beings could express their individuality. Individuality here referred to a person's singular capacity for thinking and acting. Individuality was part of modern society's collective consciousness. Collective consciousness referred to a body of ideas, attitudes, beliefs, and practices shared by all members of a society and which determined the relations of individuals to one another and society. A cult of the individual, which promoted the dignity and sacredness of the human person, emerged in support of this common belief in individuality. The problem in Durkheim's own day was that the division of labor and shared belief in individuality were unable to establish strong social bonds between people because they were centered upon maximizing self-interest. The pursuit of selfish interests and desires also did much to produce the problem of anomie. In The Division of Labor (1893) and Suicide (1897), Durkheim referred to anomie as a situation of normlessness in which the norms or rules that regulated people's lives did not function properly. When the norms and rules which kept people's goals, expectations, and desires within achievable limits broke down, people began to pursue unattainable levels of pleasure and excitement which led them to feel uncertain about goals and values. The feelings of persistent unhappiness and disillusionment caused by such uncertainty also led to a rise in the suicide rate.

Durkheim's conception of the social origins of morality also provided a useful backdrop for introducing moral individualism as a solution to the problem of anomie. Durkheim's writings on this subject were of sociological importance because they challenged the nineteenth-century ideas of Jean-Marie Guyau who positively supported the idea of anomie, and a future society where fixed moral frameworks, norms, and rules would not exist. The concept of moral individualism, which was fully developed in Durkheim's work Individualism and the Intellectuals (1898), remained the direct opposite of egoistic individualism. Whereas egoistic individualism was concerned with purely private, selfish interests, moral individualism, by contrast, stressed the importance of individual rights as a basis for creating genuinely new social bonds and common or shared identities across Western industrial societies. This transcendence of selfish interests would allow the moral ideal of individualism to attach individuals to society as never before by inspiring strong feelings of collective devotion. These feelings would in turn allow the common belief in individuality to generate strong social bonds which relieved individual uncertainties about values thereby solving the problem of anomie.

Durkheim's proposed solution to anomie in the form of moral individualism also challenged the rise of orthodox or economic forms of socialism, which attempted to solve this and other social problems in nineteenth-century Western societies by advocating a redistribution of wealth through centralized state control of the economy. Durkheim believed that these forms of socialism did not provide an adequate program for social reconstruction as the problem of anomie was neither class based nor did it have economic roots and therefore could not be solved by economic measures. The social problems facing modern society, which arose because industrialization, commercialization, and urbanization occurred too rapidly, were perceived by Durkheim as moral issues which required forms of moral authority capable of uniting individuals irrespective of their class position. Durkheim's belief that socialism was primarily concerned with economic regulation has been challenged by Giddens when suggesting that this view merely forced socialist theories into a conceptual niche which he had prepared for them.

Problems in democracy were also highlighted in Durkheim's writings. One major problem identified by
Durkheim concerned isolated individuals who made electoral choices on purely selfish grounds rather than through informed and considered opinions about current political issues. In the 1902 preface to *The Division of Labor*, Durkheim argued that this problem could be overcome through the reemergence of occupational groups or associations comprised of people who performed the same specialized work roles. These small and yet diverse functional groups would be bound together through modern society’s wider collective belief in individuality. Occupational groups would stand between the individual and the democratic state through their internal election of delegates to an elected chamber. Local representatives of the occupational group would then democratically elect other delegates to national government. This procedure removed the problem of unreflective and selfish patterns of voting by only requiring average citizens to vote on internal matters within their occupational experience. Durkheim believed that this two-tier electoral system would facilitate the Western democratic state’s reflection and effective promotion of informed opinion on the need for moral individualism in the future. Yet, as editor Robert Bellah pointed out in *Émile Durkheim on Morality and Society* (1973), this subordination of particular interests to the general interest has not occurred. Western society has not seen the revival of associational life that Durkheim originally hoped for.

Durkheim also addressed problems in education throughout his work. In *Moral Education* (1898–1899), Durkheim labeled as outdated traditional theological teachings of key elements in moral education such as the need for discipline and group attachment, following Catholicism’s failure to adjust to the growth of individuality through occupational specialization in modern society. Durkheim’s solution to this problem was to support a purely secular education for school children based upon the principles of science and reason. Secular education was needed if the historical link between moral education and mythical, transcendent forces was to be broken and the social reality behind moral rules brought to the fore. Durkheim hoped that the secular teaching of discipline and group attachment would over time enable moral individualism, and its pursuit of a genuine type of collective self-understanding, to replace traditional religion at the center of collective consciousness in modern Western society. Durkheim’s belief in the ascendancy of secular education over traditional theological teachings has not, however, been realized in Western societies at the end of the twentieth-century. Ernest Wallwork noted that theologians have not only responded in a creative way to the intellectual challenges posed by sociology, they have found new ways of using traditional language to speak meaningfully of the human condition in this world. Although Durkheim’s prediction has not yet been realized it may be premature, argued Fish, to rule out the possibility that his secular vision might come to fruition sometime in the future.

**DUTCH DISEASE**

The term *Dutch disease* refers to the adverse effects on manufacturing industries that took place in the Netherlands with the natural gas discoveries of the 1970s...
and the process of real currency appreciation that followed. Similar “illnesses” affected several oil-exporting countries following the oil price shocks of the 1970s, providing further motivation to a growing literature on the subject. In this literature a natural resource boom comes close to being a curse because specialization in natural resource intensive goods can be harmful to long-term growth.

Indeed, the development of a natural resource intensive export sector can crowd out the manufacturing sector through a number of mechanisms. First, the expansion of the natural resource sector raises labor demand in this sector, thus increasing the wage in manufacturing and reducing its profitability. The profitability squeeze in manufacturing slows down capital accumulation and growth. Second, the increase in natural resource rents generates a higher demand for nontradable goods (the spending effect in Corden 1984), which leads to a higher relative price of nontradables and thus to real currency appreciation. The higher demand for and prices of nontradables leads to a reallocation of labor away from manufacturing and into services. Third, the fall in profitability in manufacturing (especially if the nontradable sector produces inputs for manufacturing) will cause capital to move into the nontradable goods sector and the resource intensive sector. This is indirect deindustrialization because it results from the real currency appreciation caused by the spending effect and depends on its strength (see Corden 1984; Corden and Neary 1982). Finally, the increase in land endowment or in the prices of the natural resource will create an increase in the profitability of capital invested in the resource intensive sector, causing capital to move away from manufacturing and into the resource intensive sector. This resource movement is labeled “direct deindustrialization” because it is independent of real currency appreciation.

The contraction of manufacturing through each of these mechanisms may make a country worse off in the long run because manufacturing industries are those with the most externalities and rapid technical progress (Matsuyama 1992). This may happen even if the resource boom is temporary. Temporary resource booms can lead to a long-term loss of competitiveness and a lower level of per capita income than would have been the case in the absence of the resource boom (Krugman 1987).

the support of the VSN, Duvalier dismissed the military high command and brought the Haitian armed forces under civilian control. He used his militia to extend his control over all aspects of Haitian society, ruthlessly killing or exiling political opponents. Many of the Haitian ruling class, both *mulat* commercial elites and darker-skinned military men, were his victims. Duvalier also had opponents outside the country, most notably the Kennedy administration in the United States, but in the end the United States gave him grudging support in response to his unwavering opposition to communism. In 1964 he declared himself president for life. Duvalier did open up opportunities for some blacks to rise in Haitian society, but he brooked no dissent, and there was no semblance of democracy in Haiti.

When Duvalier died in 1971 his son, Jean-Claude, then just nineteen years old, succeeded him. At first, Jean-Claude was happy to be a figurehead while his mother and his father’s old advisers ran the country for him. But in 1974 he married Michele Bennet, a light-skinned divorcée several years his senior, whose father had been in prison for financial irregularities under François Duvalier. Michele enjoyed the privileges of rank, including a lavish wedding and regular shopping trips to Paris, but she also craved power for her husband and for her own family. There was a power struggle between the old Duvalierists and the supporters of Jean-Claude and Michele that ended with the retirement of Simone and many of the old hard-liners. Jean-Claude made some ineffective political reforms, and stole huge amounts of money from the Haitian state and foreign development programs. In 1983 Pope John Paul II visited the country and told the president and the Haitian people that “something needs to change here.” Priests and Catholic lay workers, motivated by liberation theology, began to work against the government. A street protest in Gonaives in 1985 turned violent, and VSN gunmen killed a dozen students. Protests broke out across the country, reacting to news carried on the Catholic Church radio station, Radio Soleil. Under pressure from the U.S. government and his own military, Duvalier agreed to step down, and he fled the country on February 7, 1986. He took with him billions of dollars of stolen money.

A transitional military government took power and promised to hold elections, but instead Haiti plunged into political chaos from which it is now only beginning to emerge. Jean-Claude and Michele lived together in exile in France for some time, plotting his return to power and fomenting disorder, but they divorced in 2000. She got most of the remaining money and remains active in Haitian politics, while he lives in modest circumstances.

EAST INDIAN DIASPORA

Indian indentured migration was a distinctively mid-nineteenth-century British labor-reallocation policy. It was predicated on and institutionalized a racial division of labor across the globe. While men and women from throughout British India were recruited during the scheme’s seven decades of operation (1836–1917), the majority were came from what are now the states of Bihar, Bengal, Uttar Pradesh, and Tamil Nadu. This policy played a significant, if under-appreciated, role in the emergence and crystallization of nationalist, nativist, and anticolonial discourses and movements, not only in India from the turn of the twentieth century on, but also in the other colonies to which men and women from the Indian subcontinent (whether under indentures or not) migrated and settled. The discursive contexts in which government-supervised indentured migration emerged was criticized, regulated, defended, and finally abolished also frame subsequent migration streams. Further, they continue to haunt the relations among the descendents of these various migrants, the Indian government, and those proliferating and polarizing transnational cultural and political economies characteristic of the early twenty-first century.

Migration around, to, through, and from the Indian subcontinent has been a characteristic and defining feature of the region’s recorded pasts. It was augmented and expanded in the colonial period by the migration and settlement of laborers, soldiers, and bureaucrats from British India to British enterprises in Burma, the Malay peninsula, and Ceylon. However, the streams currently referred to as the “Indian diaspora” are commonly understood as those that began with the mid-nineteenth-century policy of assisted indentured labor migration; that proliferated in the migrations of traders and merchants, missionaries, and teachers to serve communities of settled indentured migrants (in Uganda, for example); and that expanded in separate, but not unrelated, individual and voluntary emigrations to north America, Australia and New Zealand, and Britain and Europe. One such migration in the late nineteenth and early twentieth centuries was that of Punjabi men to the west coast of Canada and the United States (peaking from the 1890s through World War I [1914–1918]). Some of these migrants married and started families and farms with Mexican women, who were themselves participants in yet another labor emigration stream.

Another, more extended and extensively studied stream of the Indian diaspora comprises the skilled and unskilled workers and students that since the 1960s have migrated to jobs and schools in primarily Anglophone countries in the “Global North.” A further subset of the diaspora includes relocations (voluntary or under duress) of earlier migrants’ descendents. These individuals have moved from newly independent nations and former British colonies like Kenya, Tanzania, Uganda (from which they were expelled in 1972), Fiji, or the Caribbean to the United Kingdom, Canada, Australia, and the United States. Another substantial overseas migration stream from India during the last thirty years has been
that of both skilled and unskilled wage workers on short-term contracts to the oil-rich Gulf States.

Insofar as they do not result in permanent settlement or communities, the short-term migration of skilled and unskilled workers are not considered part of the Indian diaspora, either in the vocabulary of the Indian government (wherein they are designated “Non-Resident Indians,” or NRIs), or in the scholarly and popular literature on diaspora—their financial contributions to families in India notwithstanding. To distinguish these and other temporary migrants from those permanently settled overseas (sometimes for a generation or more), the government of India has coined the term “Persons of Indian Origin,” or “PIOs.”

Indentured migration from British India was a strategy (variously successful) to preserve the individual, industrial, and imperial wealth and power flowing from the highly protectionist plantation mode of sugar production in the British West Indies. While never uncontested by critics in the West Indies, Britain, or India, Indian indentured migration and the sugar plantation economy it sustained were deemed sufficiently successful to be introduced to Fiji in 1879. Indeed, in the decades before its abolition by the Indian government in 1917, indentured migration was extended to new industrial enterprises, most notably the construction and operation of railroads in the British colonies in eastern and southern Africa, where migrant and sojourning merchant communities with kinship and business ties in western India had flourished for several centuries.

Almost from its inception, the system of indentured migration was cast by detractors in India, in the labor-importing colonies and in metropolitan Britain as a “new system of slavery” (as Colonial Secretary Russell put it in a communication to Governor Henry Light on February 15, 1840). It was distinguished only nominally from the hereditary servitude it replaced. Charges of deception and coercion in recruitment in India, and of highly exploitative conditions at colonial work sites generated innumerable exposés in the antislavery press, scores of government inquiries and investigations, and ongoing efforts to devise protocols to govern the recruitment, transportation, employment, living conditions, and repatriation (or permanent residence) of indentured workers and their descendents.

Of particular concern to critics and apologists alike was the status of women among the indentured migrants, of whom a stipulated proportion (40%) was mandated by the government of India in each importing colony’s annual recruitment and allotment, despite the varied objections of employers, recruiters, and critics throughout the empire. Contemporaries and subsequent generations of observers have generally agreed that, whether indentured migration unconscionably exploited or positively benefited those who migrated under its aegis, the system helped to further institutionalize and reify categories of race, nation and division of labor, not only in broad strokes across the British Empire (and, indeed, the globe, since French and Dutch colonies also imported Indian indentured labor), but also among the various and varied populations of individual importing colonies.

Indentured migrants from British India, together with their descendents, were identified and categorized as “Indian.” Thus, men and women who may have been accustomed to identifying themselves and others according to locally significant affiliations—such as clan, lineage, village, religious practice, or language—found themselves cast as “Indian” en route to plantations (and other work sites) in the Caribbean, Africa, or the Indian and Pacific Oceans, where they would be distinguished from others encountered and cast as “African,” “Fijian,” “European,” “Chinese.” In the Caribbean colonies, for example, Indian migrants and their descendents were cast as docile, industrious, and thrifty wage laborers, in stark contrast to emancipated creole populations and their descendents, whose alleged inability or refusal to engage in plantation labor for wages provoked employers’ turn to India. That this strategy was subsidized by the colonial and imperial states did not go unnoticed by workers and critics in the sugar colonies, India, or the metropole, who charged, variously, that imported Indian labor was depressing plantation wages and forcing African-creole people out of that sector, or that it amounted to a deliberate policy of racial-national “divide and rule” on the part of employers and the state alike.

In the Fiji islands, which were brought under British protection in 1874, the bureaucratized system of Indian indentured labor recruitment and administration enabled the British government to assure Fijian chiefs that native Fijians’ exclusive rights, privileges, and identity as owners and custodians of the land would not be compromised by the introduction of plantation agriculture. The land to be brought under cultivation would be leased (and never sold) to sugar companies, and the labor would be imported (the skilled from Britain, and the unskilled—nearly 61,000 men and women between 1879 and 1917—from India).

In the Caribbean, Fiji, and indeed everywhere Indian indentured migration proceeded, large and complex bodies of legislation regulating indentured workers and Indian migrants’ personal mobility (pass laws), personal relations (stipulations recognizing as legal only those marriages performed before a magistrate or a Christian clergyman) and community organizations proliferated, further institutionalizing and normalizing indentured migrants and their communities, and separating them from others.
In addition, from the 1880s on, missionaries representing various reformist strains of Hindu and Muslim practice in India began to circulate and proselytize among the growing Indian indentured and immigrant communities in Fiji, the Caribbean and the Indian Ocean colonies, facilitating the spread of news of India to dispersed migrants, and news of the migrants to India. Together with the emergence of a specifically nationalist critique of British rule in India, this further contributed to the ongoing production and consolidation of an “Indian” identity among indentured migrants and their growing communities.

However, particularities and differences among indentured migrants (religious and linguistic ones, for example, based on where, when and how they were recruited) did not disappear en route to the importing colonies, where Hindu and Muslim immigrants pursued their separate faiths and practices in their articulate but distinctive communities. In addition, caste—and assumptions about the significance of caste and religion (as well as region of birth) to recruits’ value as plantation laborers—exercised the imagination of critics, supporters, and administrators of the system, whose observations and assessments comprise the definitive official archive on Indian indentured migration. Some employers instructed their recruitment agents in India to avoid or pursue recruits of particular castes. In 1919, an observer writing in the *Journal of the Royal Agricultural and Commercial Society of British Guiana* observed that “Excepting policemen, ex-soldiers, Brahmins, Chattris, Rajputs, Barbers, Dhobis, Nats, Banias, Fakirs, Punjabis, and coolies of any of the non-agricultural castes, all other castes are recruited and have been sent to the Colonies” (Rodway, 1919).

The data generated in the recruitment process (and preserved in the records of Indian government agencies mandated to regulate indentured emigration, which was restricted to the ports of Calcutta and Madras) have similarly attracted considerable scholarly and popular attention. These data, about which even some contemporaries were skeptical, along with data from importing colonies, indicate that the majority of indentured emigrants who left from Madras (the major port for migration to colonial Ceylon, Fiji, Malaya, Natal and Burma) were from the Tamil-speaking, eastern districts of the Presidency, while the majority of emigrants embarking from Calcutta were from what are now Bihar, Uttar Pradesh, and eastern Bengal (with some recruits from Punjab and farther east also recruited and embarked from Calcutta). The most exhaustive and critical study of these data was conducted by Sir George Grierson in 1883. His “Report on Colonial Emigration from the Bengal Presidency” suggests strongly that throughout the Bengal Presidency there was considerable awareness of what indentured migration would entail. He noted, “About caste, the people have invented a curious theory regarding ship-board life, which shows the adaptability of native customs,” in which they likened the pollutions (dietary and other) encountered on the passage from India to those encountered en route to the temple of Jagannath, a popular destination for Hindu pilgrims. He was told that “a man can eat anything on board-ship. A ship is like the temple of Jagannath, where there are not caste restrictions.”

The legal, social, and political discriminations faced by indentured migrants in other British colonies, along with the real and perceived extension of handicaps and prejudice to non-indentured overseas Indian communities, provoked intense and sustained outrage and political organization both in these colonies and in India. In South Africa, for example, members of Indian merchant communities who had settled in Natal hired Mohandas K. Gandhi to represent them in their ongoing disputes with the government between 1893 and 1914. Gandhi continued to play a role here—working on the Colour Bar and Class Areas Reservation bills of 1925 and 1926, for example—long after his return to India, despite lukewarm support from Indian nationalists focused on the struggle for self-determination at home. Those Indians in the subcontinent denied access to employment in the highest echelons of the Indian civil service and army because they were not European found it galling that, through indentured migration, “Indian” came to be associated throughout the world with unskilled and low-wage labor.

In 1912, Gopal Krishna Gokhale, an Indian nationalist leader and member of the Legislative Council (for Bombay), proposed legislation abolishing indentured emigration from India. He argued, “Wherever the system exists, there the Indians are only known as coolies, no matter what their position might be.… [T]here are disabilities enough in all conscience attaching to our position in this country, … why must this additional brand be put upon our brow before the rest of the civilized world?” (Government of India, Legislative Proceedings, March 4, 1912). The association was an important factor in the strategies and rhetoric leading to abolition of the migration scheme.

The equation of Indians with cheap labor continued to frame intra-imperial resistance to extending to India the self-rule and sovereignty accorded all the white settler colonies, even after abolition of indentureship in 1917. At the 1923 Imperial Conference held in London, for example, Prime Minister Mackenzie King of Canada argued that for his government “the problem is not a racial one; it is purely … economic.” He attributed Indians’ limited citizenship rights to the electoral clout of organized labor, which was fearful of Indians’ perceived willingness to work for wages lower than those acceptable to European-descended Canadians, and to the politics of constitutional
federalism. Referring to the legal disabilities faced by Indians in South Africa, Prime Minister Jan Smuts explained that they were merely means toward ensuring that the culture and values brought to southern Africa by European settlers in the nineteenth century continue to flourish in his country. In his comments at the Imperial Conference, he explained that white South Africans “are not there to foster Indian civilisation, they are there to foster Western civilization” (Smuts, 1988).

The implications of indentured migration’s role in the racialization or nationalization of labor through the empire extended through anticolonial struggles, independence, and beyond. In Trinidad, for example, a racialized division of labor and residential segregation (with Indian-Trinidadians predominating in rural areas and agricultural occupations, and African-Trinidadians in urban and manufacturing ones) led to political divisions between the two most numerous population groups that persisted well past independence in 1962. In British Guiana in 1957, divisions in the People’s Progressive Party (PPP) between African and Indo-Guyanese members and interests (each constituting nearly 40% of the population) led Linden Forbes Sampson Burnham to establish the predominantly African Guyanese People’s National Party (PNG). This left the PPP, led by Cheddi Jagan, primarily Indo-Guyanese. Exacerbated by Anglo-American antipathy toward Jagan’s unapologetically socialist sympathies, the racially charged political divisions were accompanied by ongoing civil unrest and violence that well lasted past independence in 1966, when a government headed by Burnham and his party took office. Indeed, these divisions were still in play after Jagan was elected prime minister in 1992.

The pattern is evident in Fiji, as well, where a military coup in 1987, led by Colonel Sitiveni Rabuka (the army is almost exclusively ethnic Fijian), produced a new constitution (in 1992) that banned Indo-Fijians from holding the post of prime minister and ensured that more than half of all Parliamentary seats were held by native Fijians. These provisions were revised in 1997, however, and Mahendra Chaudhry of the Fiji Labour Party was swept into office as the first Indo-Fijian prime minister in 1999. But a second coup, under the leadership of ethnic Fijian George Speight, toppled the newly-elected government in May 2000. Speight explained that for ethnic Fijians like himself, “it’s not so much a hate of the Indians but a fear of our host culture and everything unique about ourselves being eroded to the extent that it could be lost” (Mercer, 2000).

In the United States, passage of the 1965 Immigration Act facilitated the immigration from South Asia of professional and technical workers (as well as students seeking professional and advanced postgraduate degrees). Many of these individuals became naturalized citizens of the United States, where they and their children have been cast as “model minorities” who demonstrate the promise of American citizenship. Since the mid-1970s, patterns have shifted again, with family reunification rather than employer preference accounting for a
growing proportion of immigrants from South Asian countries. This has also led to a decline in the proportion of highly skilled and professional and technical workers among those emigrating.

In India, in the meantime, the Citizenship Act of 1955 conclusively precluded the possibility that emigrants settled overseas, whether born in India themselves or born overseas to Indian citizens, could be citizens both of their countries of domicile and of India. Instead, the act reserved to the Indian government the right to extend Indian citizenship to citizens of Commonwealth countries and the Republic of Ireland on “a basis of reciprocity” and agreement between itself and the governments in question. However, in 2004, after decades of lobbying, some PIOs who may have forfeited Indian citizenship when they became naturalized citizens (or second-generation PIOs, born overseas) were permitted to pursue a partial restitution of Indian citizenship. While it withholds the right to vote, the amendment permitting “dual citizenship” promulgated in 2004 substantially facilitates financial investments and property ownership in India by eligible PIOs, in part through the Ministry of Overseas Indian Affairs (MOIA), which was formed expressly to administer to the PIO population. While the government of India estimates that emigrants from “territories that are currently within the borders of the Republic of India” numbers over 20 million people, only emigrants to sixteen countries—none of which was involved in Indian indentured migration—are eligible for dual citizenship.

EAST INDIES

The East Indies cover a wide geographical expanse in South and Southeast Asia ranging from the Indian subcontinent to the Malay Archipelago, described as the world's largest island group. Initially referring to India, these colonial demarcations of territory later comprised more than thirteen thousand islands located across the Indian and Pacific Oceans between mainland Southeast Asia and Australia. Coveted for their rich natural resources, including rubber, spices, cotton, and indigo, and their strategic location as important trading centers along the spice routes, the East Indies were colonized by Europe in the seventeenth century after the initial exploratory missions of the Portuguese and Spanish, and especially after the founding of various European trading companies. These companies carved out zones of influence named after the particular colonizing power they represented, such as the British East Indies (India and Malaysia), the Dutch East Indies (Indonesia), and the Spanish East Indies (Philippines).

Christopher Columbus's (1451–1506) miscalculation of westward navigation routes from Spain to Asia brought him to the New World instead of India. To avoid confusion with the “original” Indies (i.e., India), the terms East Indies and West Indies were applied by Europeans to highlight territorial distinctions between Indians from the East (Asia) and the West (the Americas). These territorial designations became racial designations to distinguish East Indians from their West Indian counterparts, thereby authenticating the centrality of Europe and its power to arbitrarily classify and homogenize entire populations from the non-Western world.

East Indian also became a marker of diasporic identity in North America to designate Indians from India and to avoid further confusion with indigenous Native American or First Nation peoples also known as Indians due to Columbus's navigational errors. Consequently, East Indians had to be distinguished from American Indians even though the former did not necessarily identify with the appellation East Indian on account of its specific ethnic connotations in India and the political realities of decolonization. In the postcolonial period, the blanket characterization of East Indians as colonized subjects inhabiting the East Indies became invalid with the establishment of sovereign states. The term consequently misrepresented diasporic Indians who preferred to self-identify as South Asians instead.

In India, the term East Indian refers to a specific ethnic minority from the western Konkan coast that settled in and around the area of Bombay (Mumbai) during the period of Portuguese rule in India. They were Christianized by the Portuguese and called Bombay Portuguese to distinguish them from Goans migrating to Bombay from the former Portuguese territory Goa. They may have adopted the name East Indian under British rule to show their allegiance to the British. It is therefore misleading to label all Indians from India as East Indians because of this constituency's historical and cultural specificity in India.

In addition, the label East Indian added another polemic in the West Indies, where it designated people of South Asian origin in the Caribbean. These East Indian-West Indians further exemplified the ruptures created by colonial history and its random demarcation of boundaries through misleading nomenclature.

EASTON, DAVID

1917–

David Easton has been one of the most prominent and influential political scientists in the post–World War II (1939–1945) period. He was one of the leading scholars at the heart of the behavioral revolution that sought to develop a unified empirical theory of political science to replace the traditional study of politics. Easton has also been the leading proponent of the application of systems theory to the study of politics.

Easton received his B.A. and M.A. from the University of Toronto, and his PhD from Harvard University in 1947. From 1947 to 1984, he taught at the University of Chicago, being named the Andrew MacLeish
distinguished service professor in 1955. In 1984 he moved to the University of California at Irvine, where he is distinguished research professor of political science. He has served as vice president of the American Academy of Arts and Sciences (1985–1986) and as president of the American Political Science Association (APSA) from 1968 to 1969. His 1969 presidential address is perhaps the single most influential such address delivered by an APSA president. He has also been a fellow at the Center for Advanced Study in the Behavioral Sciences at Stanford University (1957–1958), and from 1971 to 1980 Easton was the Sir Edward Peacock professor of political science at Queen’s University in Kingston, Ontario.

Easton’s first major work was The Political System: An Inquiry into the State of Political Science (1953). There he analyzed the state of political science, which he argued had become dominated by a combination of constitutional legalism and the history of ideas that tended to lapse into antiquarian historicism. As such, in comparison to other sciences, political science was theoretically moribund. Easton argued that in order for political science to become scientifically mature, it needed to internalize scientific principles and methods and focus on the empirically observable behavior of political actors. Toward that end he proposed the adoption of systems theory as the foundation for the behavioral paradigm, and much of his subsequent work (Easton 1965a, 1965b) was directed at developing systems theory in detail. By the late 1960s, the behavioral paradigm, if not systems theory per se, had become the hegemonic paradigm in American political science. Easton went on to develop a version of structural theory to augment the framework provided by systems analysis. During that same period, another dimension of his work, one that too often goes unnoticed, is his extensive empirical research on the political socialization of children (Easton and Dennis 1969).

In his 1969 APSA presidential address, Easton called for a “post-behavioral revolution,” a term misunderstood by some critics and proponents of behavioralism alike. Easton’s vision was that the scientific procedures of social science should be brought to bear on the social and political problems facing the United States, problems whose severity could not be ignored. More recently, Easton (1997) has argued that political science has become increasingly fragmented, in part because of misunderstandings surrounding postbehavioralism that have led to an abandonment of scientific principles. Despite this fragmentation, Easton claims that the resilience of the scientific foundations of political science can provide the basis for what he calls neobehavioralism, a union of behavioralism and rational choice theory. Neobehavioralism would provide the unified science of politics to which both empiricists and rational choice theorists aspire.

Whether David Easton’s recent neobehavioralist vision will have the same impact on political science as his earlier work is yet to be determined. But his contributions to and impact on the discipline of political science since the mid-twentieth century continue to be substantial and widely recognized.

ECONOMETRIC DECOMPOSITION

Ronald Oaxaca (1973) and Alan Blinder (1973) introduced a statistical tool that enables social scientists to identify the ability of a particular observable characteristic to explain the difference in the outcomes of two groups (e.g., the black-white wage gap). The tool, known as a decomposition, provides an estimate of the contribution of discrimination to the difference in the outcomes of the two groups. Prior to Oaxaca and Blinder’s innovation, researchers were only able to identify collective contribution of all observable differences in the characteristics of two groups. The decomposition has become a required tool in many social science disciplines. It is used to explain pay differences between men and women, public and private sector workers, union and nonunion workers. Most recently, the decomposition has been applied to explaining pay differences between older and younger workers, people with disabilities and those without disabilities, and the pay disadvantage that gays, lesbians, and bisexuals experience (see, for example, Rodgers 2005, Badgett 2006, Baldwin and Johnson 2006, and Adams and Neumark 2006).

Since Oaxaca and Blinder’s seminal work, numerous extensions have been developed. Using the white-black wage gap as the example, this entry summarizes the technique’s major extensions and limitations.

THE BASIC DECOMPOSITION

Oaxaca (1973) combines log-earnings function estimates for blacks and whites and standardizes the error term to construct the following expression:

\[ D_t = \bar{y}_{wt} - \bar{y}_{bt} = \Delta X_t \beta_t + X_{bt} (\beta_{wt} - \beta_{bt}) + \sigma_t \Delta \theta_t + (\sigma_{wt} - \sigma_{bt}) \theta_{bt} \]  

where the \( D_t \) denotes the total log earnings differential. On the right-hand side, the first term is the explained gap (the portion explained by differences in measured characteristics). The second term is the residual gap (the portion attributed to differences in rates of compensation to the characteristics). The remaining two terms are generally ignored, as the decomposition is usually done at the means; otherwise, the sum of the last three terms is considered the residual gap. The residual gap is interpreted as the contribution of discrimination and characteristics that have been excluded from the model. These characteristics both predict wages and are correlated with race.

Interpreting the residual gap as discrimination requires that the model contain all of the factors that predict wages. Otherwise, discrimination’s estimated contribution is biased. Little theoretical guidance exists on the selection of the characteristics that should be included. For example, some researchers control for racial differences in occupational outcomes. Yet these outcomes are influenced by discrimination. Another major issue is that the choice of weights is arbitrary. This is a problem when the weights differ across groups, generating a range of decompositions. Some efforts have attempted to utilize economic theory to provide guidance on the weight’s choice (see, for example, Cotton 1988 and Neumark 1988). In practice, researchers either present results assuming different weighting structures, or present their preferred specification and say in a note that the results are not sensitive to choice of weights.

DECOMPOSING CHANGES OVER TIME AND ACROSS GROUPS

An extension developed by Chinhui Juhn, Kevin Murphy, and Brooks Pierce (1991) is to decompose time series changes in the wage gap into four components. For example, a narrowing or widening in the white-black wage gap from year \( t \) to \( t' \), can be written as

\[ D_{t'} - D_t = (\Delta X_{t'} - \Delta X_t) \beta_t + \Delta X_t (\beta_{t'} - \beta_t) + (\Delta \theta_{t'} - \Delta \theta_t) \sigma_t + (\sigma_{t'} - \sigma_t) \theta_{bt} \]  

The change in the actual wage gap is decomposed into (1) changes in measured characteristics holding the coefficients or prices fixed; (2) changes in prices holding characteristics fixed; (3) the contribution of shifts in central tendency or the movement of the average black in the white distribution; and (4) the contribution of shifts in spread, or changes in the variance of wages (see Juhn, Murphy, and Pierce 1991 for a detailed description of how these components are constructed). Term 3 measures changes in the position of blacks in the white residual wage distribution due to changes in unmeasured racial-specific factors (e.g., discrimination). Term 4 measures changes in residual white inequality, the wage disadvantage for having a position below the mean in the white residual wage distribution. Even this decomposition contains the index number problem. Similar decompositions can be constructed using different base years or by substituting the estimated white prices with the black prices. In practice, researchers use the average across all years as the base to avoid possible extremes within any given year.

Wing Seun (1997) identifies another potential limitation to this decomposition. The procedure generates biased results if wage inequality (Term 3) and the percentile ranks (Term 4) are not independent of one another. As wage inequality expands, the term that measures the contribution of unobservable prices increases while the term capturing movements in the position of blacks falls. This problem is greatest at the tails of the distribution. As inequality rises, the tails become fatter, artificially moving blacks up in the white distribution. The bias will be larger at the lowest percentiles because of the
skewed shape of wage distributions, but bias could be present at segments of the distribution where mass points exist. Mass points are wages that are common to a significant portion of the population.

William Rodgers III (2005) constructs distribution-specific approaches to address this potential bias. His extension of the Juhn, Murphy, and Pierce residual wage procedure (1991) starts with estimating a log wage equation for year \( t \) using only whites. He then uses the estimated coefficients to construct white and black residual distributions. With these distributions, Rodgers finds the white residual wage that equals the median black wage. This location is denoted as the \( q_{tb} \) quantile. Now using the year \( t' \) white residual distribution, Rodgers finds the white residual that corresponds to the \( q_{tb} \) quantile. This residual is interpreted as the predicted year \( t' \) black wage residual, assuming that the median black’s initial year \( t \) position is preserved. The actual change, predicted change, and the ratio of the two are then constructed. This local approach can be performed at any quantile of the wage distribution, breaking the correlation between wage inequality and percentile rank.

**DECOMPOSING OUTCOMES WITHIN SPECIFIC GROUPS**

At first glance, decomposing within group differences seems like a trivial exercise, but Oaxaca and Michael Ransom (1999) show that applying the typical wage decomposition techniques within groups leads to unidentified estimates. Lack of identification occurs because one cannot identify the separate contributions of the dummy variables that are included in the model. It is only possible to identify the relative effects of the dummy variable on the gap. The size of the residual wage gap depends on the omitted reference group chosen by the researcher (see Oaxaca and Ransom 1999 for a detailed description of this econometric problem).

For example, a decomposition of the racial wage gap in the \( j_{th} \) occupation can be written as:

\[
\gamma_j = (\beta_j - \beta_w) + (\alpha_b - \alpha_w) + \frac{X_j - X_w}{\theta^b - \theta^w} (\theta^b - \theta^w)
\]

where \( j \) is a dummy occupation variable. The last term is the predicted racial gap due to observable racial differences in characteristics.

The typical approach defines the unexplained portion of the wage gap as:

\[
\tilde{\gamma}_j = (\beta_j - \beta_w) + (\alpha_b - \alpha_w)
\]

The expression represents for occupation \( j \) racial differences in the coefficients after removing the adjusted wage difference between the average black and white in the excluded occupation (the difference in each regression’s constants). The \( \beta_j \)'s denote race-specific coefficients on the \( j_{th} \) occupation dummy variables in each black and white log wage equation. The \( \alpha_j \)’s are the constants from each black and white log wage equation.

The black-white wage gap for the \( j_{th} \) occupation is not identified because it depends on the selection of the omitted reference group of any dummy variable contained in the regression. The estimates of the \( \beta_j \)'s, the coefficients on the predictor variables (e.g., education, potential experience, industry), and the \( \alpha_j \)’s, the intercepts are not robust to choice of the omitted reference group. The \( \alpha_j \) will change when different omitted groups are specified.

To achieve identification, William Horrace and Oaxaca (2001) construct three estimators. One of the estimators is written as follows:

\[
\tilde{\gamma}_j = (\beta_j - \beta_w) + (\alpha_b - \alpha_w) + \frac{X_j - X_w}{\theta^b - \theta^w} (\theta^b - \theta^w)
\]

where \( \tilde{\gamma}_j \) and \( \tilde{\alpha}_j \) are defined as earlier. The term \( x_j - x_w \) denotes the average characteristics of African Americans in occupation \( j \) and \( (\theta^b - \theta^w) \) denotes the difference between the black and white coefficients on the characteristics of blacks and whites. This estimator avoids the identification problem because the changes in the coefficients \( (\theta^b - \theta^w) \) offset any changes in the intercepts \( (\alpha_b - \alpha_w) \). One potential drawback to this estimator is that the predicted racial wage gap varies with the average characteristics of black workers in each occupation \( (x_j - x_w) \). In order to deal with this potential problem, Horrace and Oaxaca use the means of blacks across all occupations.

Horrace and Oaxaca’s third estimator provides information about the significance of the ordered occupation wage gaps. The relative wage gap in the \( j_{th} \) occupation can be written as:

\[
\tilde{\gamma}_j = \max_{n=1, \ldots, J} \tilde{\gamma}_n - \tilde{\gamma}_j = \max_{n=1, \ldots, J} \tilde{\alpha}_n - \tilde{\alpha}_j
\]

Horrace and Oaxaca take advantage of the fact that \( \tilde{\gamma}_j \geq 0 \) and create the normalization \( \varepsilon_{\gamma} \in [0,1] \). This normalization expresses the wage gaps as a percentage of the largest normalized wage gap \( (1.0) \). The estimator removes random differences for all the excluded reference groups for all dummy variables \( (\alpha_b - \alpha_w) \) and the omitted occupation. The standard errors on the differences between the wage gaps are used to determine whether these differences are statistically significant and whether or not the order statistic has any statistical meaning.

ECONOMETRICS

Econometrics is a branch of economics that confronts economic models with data. The “metrics” in “econometrics” suggests measurements. As Lawrence Klein (1974, p. 1) pointed out, measurement alone describes only the theoretical side of econometrics. Its empirical side deals with data and the estimation of relationships. Econometricians construct models, gather data, consider alternative specifications, and make forecasts or decisions based on econometric models (Granger 1999, p. 62). Many textbooks do econometrics rather than define it, mainly because it is not all science, for it requires a “set of assumptions which are both sufficiently specific and sufficiently realistic” (Malinvaud 1966, p. 514). As with any empirical discipline, econometric model building may not precede data analysis. One may be amused to find that econometrics can be used to answer the question “Which came first: the chicken or the egg?” by the use of causality testing (Thurman and Fisher 1988). Sometimes econometricians use “a minimum of assistance from theoretical conceptions or hypotheses regarding the nature of the economic process by which the variables studied are generated” (Koopmans 1970, p. 113). Other times, econometric models such as in time-series analysis use clearly defined approaches such as identification, estimation, and diagnostics.

The tradition for introductory econometrics is to start with a single equation emanating from economic theory and knowledge of how to fit the theory to a sample of data. For example, on the economic side, econometricians have some a priori notions of the demand schedule such as the law of demand, implying that more will be bought as the price falls. This is enough of a hypothesis to allow statistical testing. The econometrician needs to confront this demand hypothesis with a sample of data, which is either time-series or cross-section.

The econometrician’s best friend is randomness. One way to appreciate randomness is to assume that the econometrician wants to explain how prices vary with the quantity sold in the form of a linear single equation model

\[ P_t = a + bQ_t + \varepsilon_t, \]

where \( P \) is price, \( Q \) is quantity, \( a, b \) are coefficients to be estimated, \( t \) is time, and \( \varepsilon \) is an error term. The error term is the main random mechanism in this model. It is normally distributed with a zero mean and a constant variance, independence of the independent variables, and uncorrelated for different sets of observations. Besides the assumptions, the error term makes the
dependent variable probabilistic, clarifying that a statistical test may not be based on the independent variables, which are not stochastic. Another requirement of randomness is that the observations should be kept sequentially in time in order to detect whether the errors are related serially, which is called “serial” or “autocorrelation” of the error terms. This is measured by the Durbin-Watson statistic, ideally equal to 2. Other preliminary diagnostic tests would require the t-statistics of the coefficients to be approximately 2 or greater, and the adjusted R-square should be in the 90 percent range. The test of a good econometric model “… should emphasize the quality of the output of the model rather than merely the apparent quality of the model” (Granger 1999, p. 62).

Besides single equations, econometricians study systems of equations models. A system of equations is necessary to capture interrelations or feedbacks among economic variables. In microeconomics, the demand and supply curves and their equality are thought of as a model to study market conditions such as equilibrium, excess demand, or excess supply. In macroeconomics, the Keynesian consumption and investment functions and a national income identity are required to study full employment and full production. A system of equations is usually solved or reduced to a single equation for forecasting purposes, which requires variables to be classified either as given (exogenous), such as the money supply and tax rates, or as variables determined by structural equations within the system (endogenous), such as prices and quantities. When the value of a variable is not in doubt at the current time, perhaps because we are relying on its previous values, then the variable is classified as predetermined. Structural equations are required in order to estimate the coefficients, whereas identity equations are required to sum up definitional terms such as that gross national product is the sum of consumption and investment. The Keynesian system of equations requires that planned savings must be equal to planned investment, which is referred to as an ex ante condition, as opposed to an ex post condition, where the variables are equal from an accounting perspective. The reduced form of the model can be used for policy purposes as instrument-versus-target models as suggested by Jan Tinbergen (1952) for the attainment of social welfare goals as suggested by Henri Theil (1961), or to simulate probable outcomes.

A system of equation models has peculiarities on both the model and the estimation sides. On the modeling side, the main difficulties reside with identification and reflection problems. Briefly stated, the identification problem requires that enough information be present in the model to make each equation represent a definite economic relation such as supply or demand. The reflection problem is concerned with getting a unique group data in order to explain individual behavior. Depending on the results of the identification problem, appropriate techniques for establishing a system of equations are available, such as ordinary least square (OLS), and three-stage least squares (3SLQ).

Some pitfalls are common to both single and systems of equations. Multicollinearity occurs when the independent variables are related, such as when one variable measures activity for a day and another variable measures the same activity for a week, requiring that one is seven times the other. A dummy variable trap occurs when binary variables such as for the treatment of sex, seasonality, or shocks all add up to a column of ones.

Expectations can be treated in both single and systems of equations. An expected variable may be present in the model, which requires one to specify, before estimation, how expectations are formed. One method calls for an adaptive mechanism to correct for past errors. The most recent method of rational expectation models requires the econometrician to adjust the expected value of the variable for all the information that is available. For instance, if one's average commuting distance to work is 10 minutes, and one hears on the news that a traffic jam has occurred, an adjustment must be made to the average time for the forecast of the arrival time to be rational. Econometricians are trying to build large-scale rational expectation models to rival standard models such as the Wharton Econometric model, the Data Resource model, or the Federal Reserve Board U.S. model, but such achievements are not in sight as yet.

ECONOMIC COMMISSION FOR LATIN AMERICA AND THE CARIBBEAN (ECLAC)

The Economic Commission for Latin America (ECLA) was founded in 1948 by the United Nations Economic and Social Council. It was given the task of facilitating development and strengthening economic ties within the region and between the Latin American countries and the rest of the world. The main venues for promoting these goals have been seminars, the funding and broad dissemination of developmental research and policy options, and the compilation of an ongoing and comprehensive database on region-wide and individual-country economic performance.

The name of the commission was officially changed to the Economic Commission for Latin America and the Caribbean (ECLAC) in 1984, when the Caribbean subregion was added to its mandate. One of the United Nations’ five regional commissions, ECLAC is also frequently referred to by its Spanish acronym, CEPAL (Comisión Económica para América Latina). Headquartered in Santiago, Chile, it also maintains subregional offices in Bogotá, Brasilia, Buenos Aires, Mexico City, Montevideo, and Port-of-Spain.

THE STRUCTURALIST PARADIGM

During its first fifteen years of existence, ECLA was directed by the Argentine economist Raúl Prebisch, who had authored a highly influential work titled *The Economic Development of Latin America and its Principal Problems* (published in English by ECLA in 1950). Frequently referred to as the “structuralist manifesto,” Prebisch’s work addressed the growing gap between the core of wealthy industrialized countries that dominated the world economy and the much larger group of poor, underdeveloped countries that sat on the global periphery. For Prebisch, this asymmetrical relationship between rich and poor countries in the global economy was due to the very structures of trade and technological adaptation that distinguished these two groups of countries, as well as to the self-perpetuating nature of the relationship between North and South.

Prebisch and his ECLA colleagues argued that the phenomenon of chronic underdevelopment within Latin America was due to the predominant reliance of countries within the region on exporting primary commodities to the United States and western Europe. In turn, Latin America was highly dependent on these northern industrial trading partners for the import of manufactured and technology-intensive goods. Over the first half of the twentieth century, commodity-exporting countries in the South were plagued by price volatility, demand fluctuation, and periodic natural disasters that adversely affected their ability to export. At the same time, the northern industrial countries were experiencing a steady upward price for the manufacturing goods they were exporting to Latin America, as technological innovation and labor productivity rendered this group of countries ever more competitive.

Throughout the 1960s, ECLA analysts defined this tendency for Latin America to pay increasingly more for imports from industrial countries and to earn less for primary exports as a problem of unequal exchange. Although subsequent economic analyses have shown these particular ECLA claims concerning unequal exchange between North and South to be exaggerated, this diagnosis stands as the overriding theoretical contribution made by ECLA. Given the heavy weight afforded by ECLA to these structural bottlenecks, a major policy prescription was to restructurize the region’s terms of trade with the North by laying down a viable and competitive industrial base.

The heyday of Latin American import substitution industrialization, whereby countries such as Argentina, Brazil, Chile, Mexico, and Peru raised tariffs on industrial imports and offered generous state subsidies to spur domestic manufacturing production, coincided with the ECLA paradigm up through the 1970s. However, ECLA’s main contribution was more the diagnosis of the underlying causes of underdevelopment and less the actual policies for rectifying it. In its early years, for example, ECLA was quite prescient in identifying such causal factors as the pattern of oligopolistic ownership within industrial-country markets and an adverse shift in the international division of labor, both of which worked against the ability of the developing countries to catch up with the North. But, in the end, the kinds of industrial policies that were pursued to counter these barriers and the specific sectors targeted for success were more a matter of domestic politics and policy choices within countries in the region.

ECLAC: A RESPONSE TO CHANGING THE TIMES

By the 1980s it would have been difficult for even the most sympathetic ECLAC analyst to put a positive spin
on Latin America’s efforts to industrialize via import substitution during the post–World War II era. With the advent of the 1982 Latin debt crisis and the plummeting of growth across the region, the shortcomings of this model were all too apparent. Over time, government-sponsored subsidies and high industrial tariffs had spawned powerful urban coalitions across sectors that succeeded in sustaining the import-substitution model despite its obvious failure to promote productivity, growth, and higher living standards across Latin America. As fiscal and exchange-rate policies favored urban manufacturers over rural producers, the agricultural sector languished, and resource-rich countries like Argentina, Mexico, and Peru could only meet domestic needs by importing food.

As import substitution collapsed under the weight of the debt crisis, ECLAC’s emphasis shifted in the 1980s. The agency concerned itself with macroeconomic recovery and the kinds of social policies that would do the most to cushion Latin America’s poor from the impacts of a decade-long recession. With the widespread structural reforms and restoration of growth that finally occurred in the early 1990s, ECLAC became an important advocate for greater technological adaptation and the need for enhancing competitiveness in the region. Interestingly, ECLAC’s earlier misgivings concerning the role of free trade and comparative advantage in the development process were eclipsed as the agency became a tripartite partner, along with the Inter-American Development Bank and the Organization of American States (OAS), in promoting the negotiation of a Free Trade Area of the Americas that would include all thirty-four democratically elected countries in the region.

**ECLAC’S INTERNATIONAL SWAY**

While the original analyses conducted by ECLAC at its inception were specific to Latin America, the academic literature on other developing countries in Asia and Africa has clearly borrowed and been enriched by the ECLAC paradigm. From the application of theories of unequal exchange to the structuralist critique of industrial-bloc dominance of international commodity and labor markets, ECLAC has left an indelible print on the fields of development economics and area studies.

**ECONOMIC CRISES**

An economic crisis is typically defined as “a turning point for the worst.” It refers to a period when “good times” turn quickly into “bad times,” when economic agents panic, leading to economic dislocation. The dislocation is the crisis—for instance, from the upper turning point of the business cycle to its immediate aftermath, until people’s expectations improve.

The history of crisis theory has a long and distinguished pedigree, ranging from Marxist economics, business-cycle analysis, and social and political analysis (Clarke 1994). There are various types of economic crises, ranging from cyclical crises to structural crises of the long wave and financial crises. These crises are interrelated with other types of crises, such as legitimization crises and, indeed, personal crises.

This entry will begin by discussing economic crises associated with business cycles. Cycles undergo upswing when economic growth, investment, and consumption are growing at respectable rates. Such cycles take various forms, as Joseph Schumpeter (1883–1950) pointed out, but if we take the typical eight-to-eleven year (Juglar) cycle as an example, factors start to negatively impact on growth as the upswing slows down. These factors variously include speculative bubbles, which eventually burst; higher costs of production, such as real wages, materials and oil, interest rates, and rent; and inadequate demand impinging on the process.

These myriad factors reduce the rate of profit before the upper turning point of the cycle. Eventually, this declining profit rate impacts on investment as businesses realize that underlying profitability has declined, and they react by reducing the rate of accumulation. Consumers, in turn, usually reduce the rate of consumption expenditure. This decline in demand then transmits into an economic crisis at the upper turning point of the cycle, leading to declining confidence, a deteriorating business environment, lower consumer confidence, and a degree of overreaction in the markets. This overreaction is a critical...
element of the crisis, as people often panic, selling their stock and reducing business activity. Such overreaction occurred, for instance, in the early phases of the (Juglar) recessions of 1974 to 1975, 1982 to 1983, 1990 to 1993 (1997 to 1998 in Asia), and 2000 to 2002 throughout much of the world.

Typically, the economic crisis also leads to or is associated with a financial crisis (especially during long-wave downswings). Martin Wolfson (1994) has shown that during the early phases of recession, the (U.S.) economy undergoes a financial crisis as the declining profitability, confidence, and animal spirits lead to a massive devaluation of capital and banking assets, causing consumers and businesses to withdraw such assets from financial institutions (and sell them off) and effectively engaging in a run on the banking and financial systems. Financial crises tend to moderate as lender-of-last-resort facilities are utilized to rescue the system from negative chains of bankruptcy, as Hyman Minsky (1919–1996) recognized. The crisis thus encompasses the early months of a recession, including financial crisis.

Crisis are usually reserved for the most protracted periods of uncertainty, instability, and panic. Some analysts may extend the short-cycle crisis to the remaining months or years of recession, but this view may be problematic because, after a while, expectations tend to improve, leading to a recovery in the cycle. Slowly, investment and consumption demand pick up as bubble crashes moderate along with costs of production and perceptions.

Karl Marx (1861–1863) differentiated between the potential for crises and the necessity of crises. The potential for crises emanates from money and credit, which enable buying and selling to be separated, leading to realization problems. The goods may be “exchanged” before the payment of “money,” due to the existence of trade credit, promissory notes, IOUs, credit cards, and so forth. The market enables potential circulation crises to emerge through supply-demand coordination failures as the final payment of money fails to materialize due to insufficient demand and over-indebtedness.

The necessity for crises, according to Marx, lay in “the very nature of capital.” The clash between competition and monopoly, for instance, leads to innovation, which starts rounds of productive investment, imitation, and gradually excess competition and low profits, leading to crisis. The conflict between capital and labor during cycle upswings may variously lead to a diminished reserve army of labor, high wages, and low productivity, and thus low profits and economic crisis. The conflict between industry and finance will periodically lead to speculative bubbles rising and crashing, and thus to economic crisis. Marx saw these contradictions of capitalism as necessarily leading to crises, which may perform the useful functions of flushing out unproductive capitals and providing the basis for renewed accumulation after a period of crisis (Mattick 1981), except in the severest types of crisis.

The possibility of severe crises is associated with problems of: (1) debt deflation, (2) insufficient demand, and (3) structural crises of capitalism. Debt deflation, according to Irving Fisher (1867–1947), is endogenously generated through a series of interrelated processes. Innovation that is financed largely by debt in an environment of endogenous money often leads to speculative excess and euphoria, resulting in the liquidation of debt, greater uncertainty, declining velocity of money, falling prices, depression, and disarray. The psychology of business is important to this process; debt deflation occurred, for instance, during crises and panics in the United States in 1837, 1873, 1893, and circa 1929, in Japan from 1990 to 2003, and so forth. Fisher saw debt deflation as counter to laissez-faire and caused by the paradox of “over-indebtedness [being] so great as to depress prices faster than liquidation, [while] the mass effort to get out of debt sinks us more deeply into debt” (Fisher 1933, p. 350). He saw policy efforts toward reflation, consistent with the New Deal in the United States, as being potentially able to tackle such problems.

This is linked to the crisis theories of John Maynard Keynes (1883–1946) and Michał Kalecki (1899–1970), both of whom saw deficiency of demand as the principal momentum underlying the trend toward economic crises. For Keynes (1936), capitalism is inherently unstable because uncertainty emanates from investment in capital assets with a prospective yield linked to future prospects, knowledge of which is close to zero. In such an environment, investment is usually determined by the prevailing business climate, which generates waves of upward and downward accumulation through history. These cycles and waves of investment variously generate overproduction as the euphoria of upswing expands prospective yield (minus supply price) beyond fundamentals, with downswings manifesting in insufficient aggregate demand linked to stock market crashes, deep recessions, and depressions. Such instability leads to periods of moderate economic crises during the short cycles and more intense crises during the longer-wave downswings.

Kalecki (1971) was able to demonstrate technically how insufficient demand generates such crises from the investment-consumption dynamics of capitalism. For instance, in a simple model, “capitals get what they spend” and “workers spend what they get.” Profit, the critical variable affecting growth, depends upon the propensity to invest, which is affected by uncertainty. Uncertainty, however, is endemic in the system as a result of deep capital projects and speculative tendencies. The severity of crises, therefore, ultimately depends upon the intensity of
this uncertainty, and the extent to which overproduction leads eventually to insufficient aggregate demand and instability.

Structural crises, the deepest and most prolonged form of crisis, are linked to long waves of development and relative demise (O’Hara 2006). Long-wave upswing typically occurs when institutions and technology are developed, leading to twenty or thirty years of higher than average growth without major financial crises or deep recessions. This approximates the era of the bourgeois revolutions in France and the United States; the Industrial Revolution of the late 1700s and early 1800s; the American and Australian gold rushes along with the “age of capital” of the 1850s to early 1870s; the period of industrial consolidation and business expansion of the late 1890s to 1910s; the postwar boom of the 1950s to early 1970s (O’Connor 1984); and possibly the age of the Internet, biotechnology, and sustainable energy during the second and third decades (at least) of the twenty-first century.

However, as institutions undergo demise and technologies mature, long-wave downswings occur for twenty or thirty years. These are the structural crises of capitalism, when profit rates, growth, investment, and (usually) standards of living for the masses have stalled. Hence the long periods when cyclical recessions and financial crises are deeper than usual: 1820 to 1850, 1875 to 1895, 1920 to 1945, and 1973 to the early 2000s. These structural, accumulation crises are long periods of above-average uncertainty, when the business outlook is generally negative (although short-cycle booms can be quite buoyant before the periodic crash). They also tend to lead to legitimation problems for many vested interests, including governments, businesses, institutions, and individuals. Personal crises tend to escalate during these times, along with social dislocation. Lender-of-last-resort facilities and big productive governments are quite likely needed to moderate such crises through raising the floor of cycles and reducing instability.

There is room for a better understanding of economic crises. More studies are needed to comprehend the early stages of recession; the linkages between economic and financial crises; and the relationship between business-cycle crises, debt deflation, insufficient demand, and structural crises of capitalism. There is also a need for further research on ways of moderating these crises and how the crises themselves may (in certain circumstances) be useful to clear the way for change and development.

ECONOMIC GROWTH

The improvement of a society’s living conditions is a complex process whose study has been at the very origins of economics. This process is called economic growth. In Western civilization, the first attempts to comprehend the mechanism of growth are recent, dating back to the end of the Renaissance only. We owe them to Giovanni Botero (1540–1617), Maximilien de Béthune, Duc de Sully (1560–1641), and Josiah Child (1630–1699). Why not earlier? Because the Middle Ages were doomed by endless conflicts and plagues; in the fourteenth century alone,
more than one-third of the European population was wiped out by the great plague. It would have taken a bold thinker to even entertain the idea of development. As the French historian Pierre Gaxotte (1895–1982) wrote: “The man of the Middle Ages does not know of time and numbers” (1951, p. 237).

It is not surprising therefore that we owe to Arab civilization the first known comprehensive explanation of the fundamental causes of economic growth. They were given in a masterly way by Ibn Khaldūn (1332–1406) in his Muqaddimah: An Introduction to History (1377). Ibn Khaldūn’s objectives went beyond explaining economic growth; he gave himself the formidable task to unveil the causes of the rise and decline of civilizations. The British historian Arnold Toynbee (1889–1975) commented about Ibn Khaldūn’s magnum opus that “in the Prolegomena to his Universal History he has conceived and formulated a philosophy of history which is undoubtedly the greatest work of its kind that has ever been created by any mind in any time or place” (Toynbee 1935, Vol. III, p. 322).

Western civilization would have to wait four centuries to see the independent blossoming of very similar ideas in Adam Smith’s (1723–1790) Inquiry into the Nature and Causes of the Wealth of Nations (1776). Today, economic theory has vindicated the conjectures made by these major thinkers, as will be discussed in the last section of this entry. Before that, the entry will explain how growth is measured, what the process of economic growth is, and how optimal growth can be achieved.

MEASURING ECONOMIC GROWTH

The standard, international measure of economic growth is the increase in real income per person (the increase is a percentage rate per year). By income is meant national income; this concept is derived from the gross domestic product (GDP), which is closely related to the measure of economic activity.

There are three conceivable approaches to measuring society’s economic activity. The result of this activity can be considered in terms of the amount of goods and services that society manages to put at its disposal within a given time span (e.g., one year). Broadly speaking, it is customary to distinguish consumption goods and services (produced for their own sake, these will not be transformed at a later stage, and are not used for manufacturing other goods or services) from investment goods. Examples of the latter are equipment, factories, and transportation infrastructure, which will be used for production in coming years. The investment goods will be added to the capital stock in existence; along with technological progress, they will play a major role in the growth process. Exports are added to consumption and investment, since they also reflect society’s activity. Naturally, consumption, investment, and even some exports include various amounts of imports; these are finally deducted in order to achieve a first measure of GDP from an expenditure point of view.

A second, equivalent, way to measure economic activity is to count the contribution of each sector of the economy (e.g., agriculture, industry, and services). Since the production of one sector (e.g., aluminum) may be used in another sector (automobiles), double counting must be avoided. For that purpose, only the net production of each sector is taken into consideration, in the form of its added value, equal to its total production less all purchases to other sectors. The sum of the added values of all sectors is then equal to GDP viewed from the production perspective.

Finally, it is clear that the only source that can be used to remunerate the production factors (labor and capital) is the value-added of each sector. In the third approach to measuring GDP, all categories of income are counted: labor income, capital income (interest and rentals paid by firms), and profits. Income used in measuring the growth of an economy is real net national income, determined as follows. First, the yearly depreciation of capital is deducted from the gross domestic product to obtain the net domestic product. We then add all capital and labor income received from abroad by residents, and dedsue payments of capital and labor income made abroad to nonresidents. We thus obtain the net national product.

Two further corrections are needed to obtain the income distributed to society: First, we deduct all indirect taxes (paid by firms) and add subsidies (received by individuals and firms). The result is called national income. Finally, we are less interested in national income than in its purchasing power. To that effect, statisticians attempt to measure the average relative price increase of the various pieces of GDP from the expenditure side, and they deflate the yearly national income by that amount. For instance, suppose they estimate that prices have increased from year $t$ to $t + 1$ by 10 percent; they will divide the year’s $(t + 1)$ national income by 1.1 to obtain real national income with reference to year $t$ as a base.

THE SIGNIFICANCE OF INCOME PER PERSON AS A MEASURE OF WELFARE

How much can we rely on income per person to gauge a society’s standard of living and its progress? This type of measure shows defects that may be detrimental to its significance. Indeed, many expenses are counted in GDP (as well as in national income), although they should not be if we are interested in measuring society’s welfare. For example, all expenditures forced upon individuals should be excluded.
from the measure. These include all public expenses made by authoritarian regimes that would not have received the population's approval through parliamentarian representation. Also included in this category are public expenditures made in countries where democracy is weak. In such countries, for example, the level of military expenditure is often far above what the country would require for pure defense purposes. These unwanted public expenses replace those that the population would have chosen, namely, expenditure for health and education.

We also count in GDP and national income a number of expenses that individuals may choose of their own free will, but which are also sometimes forced upon them by unwanted circumstances. Security expenses—security taken in its largest meaning—is an example. Those expenses are considerably higher today than they were decades ago, and of course have nothing to do with well-being. Think also of expenses resulting from accidents, disease, or epidemics. Each of the above has two negative effects upon society's welfare. First, society suffers directly from these circumstances and events. Second, those expenditures replace the goods and services that society could have enjoyed instead. No account is taken of working conditions in the measurement of national income. In particular, no account is taken of forced labor, particularly the labor forced upon women and children.

Furthermore, no equity measure appears in national accounts. This entry defines equity as the ability for society to reward each individual according to his or her own qualities and effort, and at the same time protect those hurt by fate.

Finally, national income does not account for damage done to the environment, and more generally to the biosphere. Inasmuch as depreciation of capital is deducted from GDP to obtain, after other adjustments, national income, we should also deduct the cost of the damage to the biosphere due to economic activity.

Despite these reservations, income per person remains a reliable gauge of society's welfare. If not an absolute measure, it is an adequate relative measure, since one can still make international comparisons based upon it. The fundamental reason is that the level of income in any country is intimately linked to its level of democracy. If one establishes a list of countries ranked according to their level of democracy, and set beside another list on the basis of real income per person, there would be a great similarity in both lists. Economic growth has steadily accompanied societies that have—however slowly—managed to protect the individual and have abided by the principle of equality of opportunity. A third ranking of countries according to their welfare would be very similar because democracy is highly correlated to welfare. This is the reason why it is reasonable to measure welfare by income per person, imperfect as that index may be.

### THE GROWTH PROCESS

The growth process has been well understood for at least two centuries, and can be described as follows. At the beginning of some time period—for instance, year $t$—any given country has a capital stock $K_t$ at its disposal, and a workforce $L_t$, which may be proportional to the population. This workforce enjoys a degree of technological knowledge inherited from the past, just as the stock of capital has been accumulated in the past. During year $t$, society makes use of those resources to turn out a product referred to earlier as the GDP. Part of the GDP is used to replace the capital stock $K_{t+1}$, inherited at time $t$, which has depreciated during that year. Subtracting depreciation gives the net domestic product, which can be divided into two parts: By far the largest is consumption (perhaps 85%); the rest is net investment, which is equipment that will be added to increase the capital stock at the beginning of year $t+1$. In the same time span, the labor force may have increased from $L_t$ to $L_{t+1}$, and technological advances may have been made, carrying the technological capabilities to a new level. This enables society to acquire a higher net domestic product in period $t+1$.

It is clear that the resulting increase in income will depend both on the size of net investment made in year $t$ and on the possible technological advances that the labor force may have made. Two fundamental questions now may be asked. Under what conditions will income per person increase? In other words, under what conditions will the economy grow? And if growth is to be observed, can we expect growth to continue indefinitely? The answers to these questions require a quantitative description of the economy and the building of a model of the growth process. This requires making hypotheses on the functioning of the economy, on society's behavior, and on population growth.

First, the functioning is described by a production function linking capital $K_t$, labor $L_t$, and technological progress to production $Y_t$ (which is considered equal to income) at any time $t$. This relationship can be written as the three-variable production function $Y_t = F(K_t, L_t, \theta)$, where $F$ is homogeneous of degree one in $K$ and $L$. This hypothesis means that if at any point in time $t$, $K$ and $L$ are multiplied by $\lambda$, then $Y$ is also multiplied by $\lambda$: We have $\lambda Y_t = F(\lambda K_t, \lambda L_t, \theta)$. For instance, if $\lambda = 1.1$, it means that if $K$ and $L$ both increase by 10 percent, then $Y$ also increases by 10 percent. A common, simple example of such a function is the Hicksell-Cobb-Douglas function proposed by the Swedish economist Knut Wicksell (1851–1926) at the turn of the nineteenth century: $Y_t = K_t^\alpha L_t^{1-\alpha} e^F$. The function is homogenous of degree one,
and technological progress is taken into account in the exponential term $e^{g t}$, where $g$ is $(1/Y)\frac{\partial Y}{\partial t}$, the rate of growth of income when $K$ and $L$ are constant (e.g., $g = 1.5$ percent per year).

A second hypothesis reflects the behavior of society with regard to saving and investment; one possibility is to posit that society saves and invests a fraction $s$ of its income (e.g., $s = 0.1$ or 10 percent). Investment $I$ being the rate of increase of capital, we then have $I = dK/dt = sY = sF(K, L, t)$.

Finally, the last hypothesis is about the growth of the population (considered as the labor force). The growth rate of the population is supposed to be constant and equal to $n$ (e.g., $n = 1\%$ per year). Equivalently, it means that $L_t = L_0 e^{nt}$.

With these three hypotheses, we have a complete, albeit simple, model of the growth process. Observe that the rate of increase of capital, $I = dK/dt$, is a linear function of income, $Y = F(K, L, t)$, and the stock of capital $K_t$ is driven by the differential equation,

$$I = \frac{dK}{dt} = sF(K, L, t). \tag{1}$$

In the example above, we would have

$$\frac{dK}{dt} = sK^n \left( \frac{L}{L^n} \right)^n. \tag{2}$$

Equation (2) is a Bernoulli equation that can be easily solved, leading to a trajectory of capital $K(K_0, t)$ which depends on the initial value of capital $K_0$ at some point of time $t = t_0$. In turn, this capital time path can be plugged into the production function $Y = F(K, L, t)$ to yield the time path of $Y$, as well as the evolution of income per person, $y = Y/L$, our variable of foremost importance.

In fact, a general, qualitative picture of the evolution of the economy can be drawn by making clever use of a fundamental property of the production function, as Robert Solow did in "A Contribution to the Theory of Economic Growth" (1956). Observe that if $\lambda$ is replaced by $1/L$ in $\lambda Y = F(\lambda K, \lambda L, t)$, then $y = Y/L = F(K/L, 1, t)$, which depends now solely upon the capital-labor ratio $r$ and time. Suppose for the time being that there is no technological progress; then $y = f(r)$, and income per person is simply a function of $r$. This function is always increasing, if $Y = F(K, L)$ and $Y/L = f(r)$, $Y = Lf'(r) = Lf'(r) / (1/L) = f'(r)$. Assuming that the marginal productivity of capital $\partial Y/\partial K$ is positive leads to $f'(r) > 0$. This result is of central importance, because it means that the evolution of income per person is driven by the evolution of the capital labor ratio. Thus, the qualitative evolution of $r = K/L$ will enable us to reach conclusions as to the evolution of income per person, and to answer the second question we asked at the beginning of this section. This can be achieved for very broad families of the production functions, without resolving the differential equation (1), nor knowing the exact mathematical specification of $F(K, L, t)$.

Consider the rate of increase of $r(t)$. Denoting $K = dK/dt$ and $L = dL/dt$, it is

$$\frac{d}{dt} = \alpha K = \frac{dK}{dt} = \frac{KL - KL}{L} = \frac{K}{L} - \frac{K}{L} = \frac{K}{L} - nr.$$

Since $K = I = sY$, we have finally,

$$r = sy - nr \tag{3}$$

which is the fundamental equation of positive economic growth. It has an immediate economic interpretation: The rate of increase of the capital-labor ratio is the difference between investment per person ($sy/L$) and the investment per person that is necessary to maintain the capital-labor ratio constant ($nr$); indeed, if $L$ grows at rate $n$, and if $K$ is to grow at the same rate ($K/L = n$), then $K(= I)$ must be $nK$, and investment per person $K/L$ must be $nK/L = nr$. It is obvious that $r$ will increase ($r > 0$) if and only if investment per person ($sy$) is higher than the investment per person necessary to maintain $r$ constant ($nr$). Now equation (3) is a differential equation in $r$, but it does not need to be solved in order to infer the evolution of the economy and its ultimate outcome. Only a picture—a phase diagram—is required. We can simply draw the curve $sy = sf(r)$ and the ray $nr$, and consider the difference, $r = sy - nr$, which will be the rate of increase of $r$. This is done in Figure 1.

![Figure 1: The phase diagram of the growth process.](image-url)
Suppose that, initially, the capital-labor ratio is \( r_0 \). We can immediately see that \( r \) is positive at that point; therefore \( r \) will increase, and income per person will increase as well. This process will drive \( r \) toward its equilibrium value \( r^* \), where \( r = 0 \), and therefore \( r \) stays constant. (Whether \( r^* \) will be reached or not cannot be inferred from the simple reading of the phase diagram. Solving the corresponding differential equation is required; it can then be shown that \( r^* \) is reached asymptotically only—that is, when \( t \) tends to infinity.) On the other hand, if the initial value \( r_0 \) is above \( r^* \), then \( r < 0 \); \( r \) will decrease toward \( r^* \).

If the marginal productivity of capital \( \partial F/\partial F = f'(r) \) diminishes in such a way that the curve \( s(r) \) intersects the ray \( nr \), then the economy will tend toward a fixed, equilibrium point \( (r^*, f(r^*)) \). Therefore, income per person is bound to tend toward the limit \( y^* \).

Two circumstances, however, may arise in which this phenomenon will not occur and income per person is not bounded. The first possibility is that the curve \( s(r) \), concave as it may be, will not intersect the ray \( nr \). Such a possibility may arise if the elasticity of substitution between capital and labor is sufficiently high (the elasticity of substitution measures the ease by which capital may be substituted with labor to achieve a given level of output when the price of labor increases relative to the rental rate of capital (on this concept, see La Grandville 2007b)). Then, the curve \( s(r) \) tends asymptotically toward a ray with a slope equal to or larger than \( n \). If that is so, there will be no intersection between \( s(r) \) and \( nr \); \( r \) will always be positive, and \( r \) will always grow.

The second circumstance that may lead to permanent growth is the very existence of technological progress. Indeed, suppose that \( f(r) \) is multiplied, as in our previous example, by \( e^{rt} \). It means that in Figure 1 the curve \( f(r) \) is constantly shifted upward by the mere force of technological progress. It implies that even if, in a first phase, capital labor is decreasing, it will ultimately increase, carrying with it an increase in income per person.

From a methodological point of view, economic growth is first described by a dynamic model that captures the motion of the economy; such models typically generate one, or a set, of differential equation(s). The next fundamental questions are: If we are confident in the validity of such models, can we determine a trajectory of the economy that would be optimal compared to other possible time paths? And how is optimality to be defined?

**OPTIMAL GROWTH**

Suppose that we are able to infer the future trajectory of an economy from the solution of the model described above. An infinity of choices are offered to society, in the sense that society can choose an infinitely large number of savings investment ratios \( s \), and to each of those corresponds a given future time path for the economy. Which is to be chosen? What would be an optimality criterion for society? A natural answer could come from what was discussed above: Society does not accumulate capital for its own sake, but it does care for the consumption goods and services that capital can provide in the future. So a logical aim for society would be to determine a time path \( K_t \) that would maximize the sum of consumption flows to be received in the future, with an important proviso: A consumption flow received in thirty years is to be valued less than the same flow received much sooner. Accordingly, such future consumption flows have to be discounted, and a discount rate that would reflect society’s rate of preference for the present must be defined. Furthermore, following Frank Ramsey’s (1903–1930) opening treatment of the subject in 1928, it was proposed that consumption flows \( C_t \) should be transformed into utility flows through some concave, increasing, utility function \( U(C_t) \). Thus, for about three-quarters of a century, the problem of optimal growth was defined as follows: find a trajectory \( K_t \) that would maximize the integral

\[
\int_0^\infty U(C_t)e^{-\alpha t} dt
\]

subject to the constraint

\[
C_t = F(K_t, L_t, t) - K_t
\]

which is equivalent to maximize

\[
I = \int_0^\infty [F(K_t, L_t, t) - K_t]e^{-\alpha t} dt. \tag{4}
\]

This fundamental problem of optimal growth belongs to the calculus of variations, an extension of differential and integral calculus. Differential calculus deals, among many other things, with the optimization of functions, that is, relations between one or several variables and a number. The integral in (4) does not have that characteristic; rather, (4) is a relation between a whole function \( K_t \), for \( t \) between 0 and \( \infty \) and a number \( I \). Such a relationship has been given a special name: a functional. The calculus dealing with functionals is the calculus of variations because the increase of a variable in differential calculus is now replaced by the variation of a whole function. This branch of mathematics was born when Johann Bernoulli (1667–1748) submitted in 1698 to his fellow mathematicians the problem of finding the curve joining points \( A \) to \( B \) such that a bead sliding along the curve would reach \( B \) in minimum time. The problem was solved by Bernoulli himself, his brother Jacob (1654–1705), and also by Gottfried Wilhelm Leibniz (1646–1716), Isaac Newton (1642–1727), and Guillaume de l’Hôpital (1661–1704), each using different methods. A general method of solving variational problems however had to wait for the genius of Leonhard Euler (1707–1783), who in 1744 showed that if a functional \( \int_a^b G(K_t, K_t, \dot{K}_t) dt \) is to

Economic Growth
be maximized, a first-order condition is that it satisfies the differential equation
\[
\frac{\partial G}{\partial K_i}(K, \dot{K}, t) - \frac{d}{dt} \frac{\partial G}{\partial \dot{K}}(K, \dot{K}, t) = 0 \tag{5}
\]

Equation (5) is generally a second-order, nonlinear differential equation. Its second-order character comes from the fact that the second term on the left-hand side of (5) is the total derivative of \( G(K, \dot{K}, t) \) with respect to \( t \), which will generate a term depending on \( K, \dot{K}, \) and \( t \), \( G_{K\dot{K}} \), multiplying \( \dot{K} \).

Applied to the problem of optimal growth, the Euler equation yields,
\[
i(t) = F_t'(K_i, L, t) + \frac{U_c'}{U_c'}
\tag{6}
\]

The Euler equation (6) unfortunately is seldom solvable analytically, and this is precisely the case here. Only numerical analysis is available to determine the optimal trajectory \( K^* \), from which optimal investment \( I^* = \dot{K}^* \), income \( Y^* = F(K^*, L, t) \), and finally savings rate \( s^* = I^*/Y^* \), can be deduced. The difficulty of solving the problem numerically led economists to keep it in the realm of theory. The problem with this situation is that short shift was given to the fact that each time some numbers were obtained, the strangest results appeared in the form of an exceedingly high “optimal” initial savings rate, often on the order of 40 percent.

With the invention of efficient computing software, it became possible to undertake a much more systematic examination of the problem of optimal growth. It was found that the culprit was the introduction of an arbitrary utility function, \( U(C) \) (La Grandville 2007a). When the objective functional is more simply the sum (the integral) of the discounted consumption flows, then two remarkable consequences emerge: First, the Euler equation is no longer a differential equation solvable only by numerical methods, but an algebraic equation from which the optimal trajectories \( K^*, I^*, \) and \( s^* \) can be derived in analytic form. Second—and more importantly—the optimal savings rate now has reasonable, reachable values.

THE FUNDAMENTAL FACTORS OF ECONOMIC GROWTH

As mentioned above, Ibn Khaldūn provided the fundamental factors of economic growth. These are not set at random, but follow a logical order, one implying the other.

Demographic Growth and Technological Progress Ibn Khaldūn’s idea is that a larger population enhances the division of labor. This view of demographic growth was rediscovered four centuries later by Adam Smith in his Wealth of Nations. In addition, the enhancement of division of labor that accompanies technological progress improves the chances that an individual, by concentrating on a specific task, will find ways to innovate.

The Search for Individual Profit The search for individual profit is a factor of growth that is far from obvious. According to Ibn Khaldūn: “Civilization and its wellbeing as well as business prosperity depend on productivity and people’s efforts in all direction in their own interest and profit” (Ibn Khaldūn [1377] 1958, p. 104). Those words were later echoed by Smith:

Every individual is continually exerting himself to find out the most advantageous employment for whatever capital he can command. It is his own advantage, indeed, and not that of the society, which he has in view. But the study of his own advantage naturally, or rather necessarily, leads him to prefer that employment which is most advantageous to the society…. He generally, indeed, neither intends to promote the public interest, nor knows how much he is promoting it…. He intends only his own gain, and he is in this, as in many other cases, led by an invisible hand to promote an end which was no part of his intention. (Smith [1776] 1977, pp. 398–400)

It is of fundamental importance that neither Ibn Khaldūn nor Smith defended the idea of using any means to make a profit. Quite on the contrary, both sternly condemned the abuse of dominant positions and monopoly power. But if profits can be made by inventing new processes or new products, how is it possible that such profits might be to the advantage of society as a whole? In addition, a further step was taken by Smith, for whom the optimum employment of capital by an individual would result in a maximum advantage for society.

Ibn Khaldūn’s and Smith’s conjecture can be illustrated and formally demonstrated. A first illustration is based upon the outcome of introducing technological progress. It can be shown that if innovations reduce marginal production costs, society’s surplus will always increase, although ultimately some firms may see their profit diminish. Enhanced productivity (to quote Ibn Khaldūn) will induce firms to produce more, thereby increasing competition among them and forcing prices down. The lower prices and increased quantity will benefit consumers. Consumer surplus will increase in such a way that it will always more than compensate for any reduction in surplus suffered by producers. A striking example is the spectacular growth of China since the late 1970s, a growth process never witnessed at any other place or time. Its origin can be pinpointed to the suppression of the popular communes by Deng Xiaoping (1904–1997)
in 1978. When farmers were allowed to increase production on private lots beyond the quota they were required to remit to cooperatives, they generated enormous surpluses for consumers and for themselves alike. Savings and investments increased on a large scale, setting in motion the growth process described in the beginning of this article. Clearly, the aim of farmers was to make a profit, but this benefited the entire Chinese economy, even though such a result had not been their intention (on this and for a formal proof of Smith's conjecture, see La Grandville 2007b).

**Private Property** The fourth factor of economic growth enunciated by Ibn Khaldūn is the principle of private property. Ibn Khaldūn lists three major transgressions to that principle. The first is slavery, condemned by Ibn Khaldūn who, to the best of our knowledge, was the first thinker to denounce what he considered “one of the greatest injustices and one which contributes most to the destruction of civilization” (Ibn Khaldūn [1377] 1958, pp. 108–109).

The second transgression against private property is private and public monopolies and, more generally, the infringement of competitive markets. (It is striking that Ibn Khaldūn also described the very system that would be implemented in many countries in the coming centuries, whereby farmers would be compelled to sell their product to a central authority that would market it at monopoly prices.)

The third transgression is excessive taxation, which destroys the desire to set up firms, and ultimately the very income that is supposed to be taxed.

**The Soundness of Political and Legal Institutions** In his *Introduction to History*, Ibn Khaldūn stressed the fundamental, necessary role that institutions play in the growth process. One of his aims was to warn his contemporaries of the dangers that lurked for their civilization if they did not manage to maintain a political system that would protect the individual. He tells us that he was not able to elaborate a better system of government than that embodied in a famous letter sent in 822 by Tahir, one of the generals of the king of Egypt, to his son Abdallah, which Ibn Khaldūn quotes in full. Here is one of its most significant messages:

> Consider it your most important task to take personal charge of the affairs of [your] officials and to protect your subjects by looking after their needs and providing for their requirements…. Do not be greedy. Let the treasures and riches you gather and hoard up be piety, the fear of God, justice, the improvement of your subjects, the cultivation of their country, the supervision of their affairs, the protection of the mass of them, and support of the unfortunate. You should know that property, once it is gathered and stored in treasuries, does not bear fruit, but if it is invested in the welfare of the subjects and used for giving them what is due to them and to prevent them from need, then it grows and thrives. The common people prosper…. Devote yourself to looking after the affairs of the poor and indigent, those who are not able to bring before you complaints about injustices they have suffered, and other lowly persons who do not know that they may ask for their rights. Inquire about these people in all secrecy, and put good men from among your subjects in charge of them. Command them to report to you their needs and conditions, so that you will be able to look into the measures through which God might improve their affairs. Have regard also for people who have suffered accidents, and for their widows and orphans. Give them stipends from the treasury, following the example of the Commander of the Faithful…. Set up houses for muslims who are ill, shelter them, [appoint] attendants in these houses who will handle them kindly, and [appoint] physicians who will treat their diseases. Comply with their desires so long as it does not lead to waste in the treasury. (Ibn Khaldūn [1377] 1958, pp. 143–153)

Prosperity, for Ibn Khaldūn, thus implies as a necessary condition the protection of the individual and at the same time a social policy that corresponds very closely to the equity principle defined above.

**CONCLUSION**

William Letwin, in his introduction to the *Wealth of Nations*, described Adam Smith's message thus: “Far from being a hymn in praise of anarchic greed, the *Wealth of Nations* is a reasoned argument for justice, order, liberty and prudent plenty” (Smith [1776] 1977, p. xxii). One could not better characterize the *Mugaddimah* by Ibn Khaldūn. The similarity of those two messages, from different civilizations and four centuries apart, prompts us to beg the question of the convergence of ideas and values among civilizations. Economic growth does require the factors enunciated by Ibn Khaldūn; it also requires peace. Ibn Khaldūn spent a good part of his life trying to negotiate peace treaties on all shores of the Mediterranean. For his part, Smith denounced wars and the financing of wars as the greatest deterrent of economic growth. In Western civilization, one of the most fundamental values is the principle of defensive war, which probably originated in the writings of Augustine of Hippo (354–430 CE). Shared by Ibn Khaldūn and Smith, did this idea appear elsewhere? Indeed, they were preceded by the Chinese philosopher Mo-Tzu (c. 470–391 BCE) (Watson 1967).
Mo-Tzu tried—in vain—to advocate this idea, which he based upon another fundamental principle: that of equality of individuals and states. This latter principle would take more than two thousand years to be slowly implemented in state constitutions, and even longer in social behavior.

Nevertheless, the last millennia definitely witnessed a convergence of ideas and values among civilizations, and such is the reason why we may hope that societies will ultimately achieve economic growth for all.

ECONOMIC METHODOLOGY

Economic methodology is concerned with how economic knowledge is pursued. It covers a range of issues: Can we establish rules for good economic analysis, and if so what are they? If we cannot establish rules, are there principles for guidance? What principles do economists use in practice? How are we to understand the evolution of the discipline? How separate is economics from other social sciences, and to what extent should economic methodology be discussed independently of the methodology of other social sciences?

The term methodology is often used incorrectly, to refer to methods. Methodologists use the term to refer to the approach taken to building knowledge (and the status of that knowledge), which provides among other things the basis for choosing methods. Some also draw the distinction between Methodology and methodology, the former being prescriptive (setting rules) and the latter descriptive (providing an account of methodology in practice). We will see that the balance has shifted over the last few decades from Methodology to methodology (see further Sheila Dow’s introductory Economic Methodology [2002], and D. Wade Hands’s more specialized Reflection without Rules [2001]).

Economic methodology is now a large specialist field in its own right. Before the 1980s, it was examined from a philosophical perspective only by a limited number of texts, drawing directly from the philosophy of science, or was discussed in the context of historical discussions of past methodological disputes. When it was discussed, as in the introductions to textbooks, it tended to be associated with a positivist philosophy of science, with an emphasis on testing theory against objective facts, and a distinction of positive from normative statements. Indeed, this was the approach taken by Milton Friedman (1953) in what for a long time was the most famous piece of methodological writing in economics. Friedman argued that the purpose of theory was to predict, regardless of the realism or otherwise of assumptions; theory was thus simply “instrumental.” This sparked heated debates with those (ranging from Samuelson to Kaldor) who saw the primary purpose of theory to be explanation, and thus considered the realism of assumptions to be important. Indeed, Friedman had drawn distinctions too sharply: In order to predict, there has to be some understanding of causal mechanisms, along with the capacity this provides to adapt theories to changing economic structures. Thus theory content is still
important. Nonetheless, the boldness of Friedman's challenge forced dissenters to formulate their methodological positions more explicitly.

Beginning with the publication in 1980 of Mark Blaug's authoritative *The Methodology of Economics*, there has been a tremendous increase in interest in economic methodology, which led to the setting up of the International Network for Economic Methodology, with its *Journal of Economic Methodology* and Web site www.econmethodology.org—which in turn have generated even more interest and activity, among both specialist methodologists and practitioners. The growth in the field also no doubt reflects a need to understand debates in economics at a deeper, foundational, level. The wide range of topics now covered by economic methodology is evident from the *Handbook of Economic Methodology* (1998).

Blaug's text appeared at a time when new developments in the philosophy of science had challenged the whole idea of establishing a single set of independent rules for good practice (monism). Blaug called on economics to build on Karl Popper's idea that, even if we cannot be certain that we have identified a true explanation, we can at least be certain of identifying a false explanation, if the evidence contradicts the theory (falsificationism). While Popper had advocated exposing all elements of theory to empirical testing, he made an exception for the axioms of rational individual behavior from which mainstream economic theory was built. These axioms specified the basis for individual choice, which in turn was the basis for the optimal allocation of scarce resources. They were necessary for setting economic theory up as a deductive logical structure, generating hypotheses that could be tested against empirical evidence (the methodology presented for many decades in introductory economics textbooks).

In the tradition of seeing methodology as prescribing good practice, Blaug drew attention to how economists' practice fell short of Popper's principles, due to a reliance (if at all) on evidence that confirmed theory—namely, verificationism. Indeed, such an approach was supported by the priority given by many to explanation over prediction. But in the meantime a divide had grown between pure theory, which was not generally tested, and applied economics, which had little impact on theory. Other methodologists shifted attention to understanding why this was so, drawing on the philosophy of science of Thomas Kuhn. In the absence of any absolute rules for good scientific practice, Kuhn had analyzed science in terms of activity within scientific communities, each of which has its own methodology and understanding of reality. Because of the latter state of affairs, we cannot think in terms of an independent set of “facts” against which theory is tested in any absolute sense.

Kuhn's ideas encouraged the development of what came to be known as constructivism, based on the idea of knowledge being “constructed,” rather than established by facts. This development encompassed postmodernism (the denial of any general knowledge), rhetoric (the focus on techniques of persuasion other than methodological principle), and the sociology of scientific knowledge (the sociological study of scientific communities). Within constructivism, “Methodology” has no role, only “methodology” as a descriptive device. A high proportion of methodological work now falls into this category.

Kuhn had also encouraged the legitimation of a range of heterodox schools of thought, which proceeded to define themselves in terms of methodological differences from the mainstream. The differences started from a rejection of the whole idea of founding theory on axioms of rational choice (or indeed any deterministic account of behavior), as such axioms did not mesh with heterodox understandings of reality. Methodological awareness is thus wider spread in heterodox economics, playing a more central role in debate. Current leading topics focus at the levels of reality and of mode of thought, that is, below the methodological level: Is reality an open system (and what does that mean), and does such a system require an open system of knowledge, and what does that imply for methodology? Should there be a plurality of methodologies, and should methodology be pluralist (employing many methods)? How far does realism allow us to specify methodological principles after all? The realism debates have moved well beyond the old debates about the extent to which assumptions should be realistic.

In the meantime, there have been new developments in mainstream economics that require methodological discussion. Experimental and survey evidence contradicting the rationality assumptions, for example, is now encouraging theoretical change. Nevertheless the change is in the direction of a more complex account of rational individual choice, maintaining the traditional logical structure of mainstream theory, with its methodology of deducing arguments by logic from axioms, to be tested against facts. Within the mainstream, economics continues to be defined by this methodology, which requires fully specified individual behavior.

Current methodological discussion is thus both diverse and wide-ranging. Much of it is “micro” in the sense of examining particular developments in economics in methodological terms. At the “macro” level, it is concerned much less with principles to guide practice and much more with principles by which to understand the discipline.

ECONOMIC MODEL

Economic models may be seen as intermediate between theories and the world, and are accordingly differently understood depending on how one sees their relationships to each. Models are specifically economic models when they address forms of social interaction involving prices and other money magnitudes. Daniel Hausman (1992) takes models to be either trivially true or neither true nor false, and thus to constitute conceptual explorations of theories. His emphasis is on theoretical models, not on empirical models, and thus on how models enable us to investigate theoretical concepts. In contrast, Ronald Giere (1988) sees science as a cognitive process, and is concerned with how models help us learn about the world. He sees the relationship between models and the world as one of similarity (though not of isomorphism). This allows models to be both somehow “true” of the world and yet at the same time not be expected to fully reflect the structure of the world.

Models may be defined, then, as instruments of investigation that allow us to concentrate on relationships of special interest, whether in theory or in the world or in combination of the two (see Morgan and Morrison 1999). That they focus attention on aspects of the world implies that they should not be taken as complete explanations, but as particular ways of examining those aspects. Within this framework, several different approaches to Giere’s similarity idea have been suggested. Models have been taken to be idealizations or approximations that provide “realistic” though partial representations of the world. Models can also be seen to be like analogies and metaphors in that they exhibit similarities between different domains or systems. Another view is that models are like stories told to explain how theories may be interpreted or how theories relate to the world.

There are a number of misconceptions about the nature of economic models. While economic models are often seen to be sets of highly formal statements, there is nothing in the concept of an economic model that requires formal representation. Indeed, whether formal models or qualitative ones are preferred depends on the subject matter being modeled. Another widespread belief is that models are essentially instruments for making predictions about the future. But models have many different uses. There are theoretical models, simulation models, policy models, econometric models, measurement models, experiment models, formal models, accounting models, and so forth, all of which are constructed for different, often highly specific, purposes. Further, even good models designed expressly for making predictions can fail to produce reliable predictions in changing environments. Thus, because economic models have both limited and usually quite specific purposes, it is important to avoid uncritical use of the information they generate. Models are instruments for all kinds of investigation, and our investigations of the world are fallible, partial, and subject to revision.

ECONOMIC PSYCHOLOGY

The field of economic psychology explores how economics impinges on the psychology of both individuals and groups, as well as how people both individually and collectively affect the economy. This transactional interplay between society at both the micro level and the more macro level of sociocultural institutions suggests that traffic between the two is not just possible but should be welcomed as a new field of study. The study of economic psychology originated in the late nineteenth century, with
contributions from the French social scientist Gabriel Tarde and the American sociologist Thorstein Veblen.

The early ambitions of individuals like Tarde and Veblen to challenge the very foundations of economics have become more modest, and one of the legacies of their critique of economics has been the establishment of psychological considerations as important in economic theory and research. The field of economic psychology is populated by a small but vigorous intellectual community in its own right. The assumptions of rationality that underpin “homo economicus” have been effectively challenged, and the cognitive biases that influence decision-making and are part of human nature are now well known in all branches of social science.

Today, marketing students are taught about the social-emotional meaning of brands and how consumption practices are driven by considerations of social identity. The economist Richard Thaler points out that money, which is said by economists to be “fungible” (i.e., one sort of money is equivalent to any other), is in fact subject to mental accounting, meaning that money is viewed differently in different contexts. For example, money received as regular income is put in a different category than money from a windfall. Fungibility is not just a simplifying assumption. It does not do justice to the ways people manage their economic affairs in the real world. People have a concept of money that is situated and context-dependent.

Economic psychology is also interested in economic behavior in different cultural and historical contexts. So economic socialization, or how children learn the ways of their own economic world, has become a thriving part of economic psychology. The developmental changes that occur as children grow up mean that any theory of their economic decision-making is inevitably dependent on their level of psychological development. In household economics, economic psychologists have been exploring money management within the family. The psychologist Carole Burgoyne has argued that the styles that families and couples adopt to negotiate their finances can reflect deep-rooted tensions and reveal significant aspects of their relationships that would be otherwise difficult to access.

There are other areas of research and scholarship apart from economics and psychology that impinge on and influence economic psychology. Behavioral economics, for example, attempts to blend together economics and psychology, though in the main it is limited to the examination of psychological aspects of decision-making and the improvement of economics by placing it on a more realistic psychological foundation. Economic sociology, on the other hand, is firmly rooted in the sociological approach to the study of society. Here, the concepts and epistemology of sociological enquiry are applied to economic institutions. The field of economic psychology will remain valid and important as long as the cross-fertilization between economic and psychological theories and practices is mutually respected, and as long as there is a will to synthesize from debates and disputes.

**ECONOMIC RHETORIC**

The expression *economic rhetoric* refers to the practice and study of the communication process of economic ideas, both in oral and written form. It conveys the notion of economics as a particular type of social discourse, one that uses analogies, appeals to authority, arguments by transitivity, and other rhetorical devices to persuade its audience.

The rhetorical nature of economics is the focus of a research program that began in the early 1980s, generating a significant amount of research, still ongoing, and eliciting much controversy. The pioneer authors were D. N. McCloskey and Arjo Klamer, who, moved by their dissatisfaction with conventional economic methodology, decided to investigate the scientific culture of economics.

Klamer conducted a series of interviews with eleven prominent economists from different schools of thought, asking them about their intellectual trajectory and the circumstances in which they came to elaborate their well-known models. He claims that theoretical disputes within economics are not settled by the accumulation of empirical evidence. Instead, Klamer suggests that a more promising interpretation of these disagreements should focus on their rhetorical aspects, the ongoing conversation through which economists everywhere try to persuade their audiences.

McCloskey also criticizes traditional epistemology. Under the influence of postmodernism and neopragmatism, she holds that the prevailing methodological approach is rooted in modernism, which views science as axiomatic and mathematical. Although the progressive mathematiza-
tion of contemporary economics allowed certain questions to be formulated with greater clarity, it involved major costs, one of them being a widespread tendency to confuse statistical significance with economic significance. McCloskey acknowledges that the change in language brought some transparency to economic arguments, but she claims that it hindered the dialogue with other humanistic disciplines and led economists to subscribe to a positivist methodology. She argues that economists should pay attention to their rhetoric, in order to gain a new self-consciousness of their conversation practices.

At the heart of the debate raised by the rhetorical turn in the history of economics lies a tension that has existed since the ancient Greeks and is not yet settled. It stems from the two potentially conflicting meanings that the word rhetoric acquires, as form and as substance, as mere ornament to speech and as a set of arguments directed at an audience. While some Sophist philosophers stressed the ornamental aspect of rhetoric, thus helping to give the concept the pejorative meaning of “mere rhetoric,” Aristotle legitimated it as a rational procedure, intimately connected to logic and dialectic. During the twentieth century, the rehabilitation of the Aristotelian tradition expressed the need for a better understanding of how a persuasive discourse works to influence its intended readers.

Still, the pejorative and dismissive meaning of rhetoric as empty speech persists. The rhetorical turn in economics was unable to give a satisfactory answer to its critics, who accused it of neglecting the truth-seeking nature of scientific inquiry. Yet it drew attention to the argumentative aspect of economics, highlighting the importance of rhetorical analysis as a research tool, to be used to show how texts conceived in a given social context create meaning, construct knowledge, and elicit action. By paying attention to their rhetoric, economists can improve the quality of their discourse.

credentials that a proposition may have, two uses of those credentials may be made: The prescriptive use postulates that one and only one set of credentials produces acceptable knowledge, while the credentialist use affirms that every proposition has its own set of credentials and that the individual is free to accept or reject it. These modes of use tend to be at the heart of competing practices, each yielding status emulation.

A second axis has to do with the fundamental substantive paradigms that tend to govern all work in economics. This axis constitutes the ontology of economics. Among the different paradigmatic possibilities are the fundamental theories of a surplus; constrained maximization (maximization subject to constraints, such as cost or legal prohibitions or requirements); productivity or exploitation; culture; and the attainment of a level of welfare and the structure of its distribution. Paradigms are among the most important elements in the social construction of economics.

A third axis concerns the fundamental problem of economics. Among the multiplicity of contenders for this designation are: the organization and control of the economic system, the efficient (or optimum) allocation of resources, economic growth, maximization of welfare, distribution of income (and wealth), and the ordinary business of life in terms of earning a living.

A fourth axis, somewhat related to the third, concerns the organization and control of the economic system itself. A central focus here is the institution of private property, while institutions such as the market, the development of the division of labor itself, and the system of social control are also relevant. One composite approach is that of the "market plus framework," in which markets exist on the basis of the framework of social controls. The identity of the framework tends to be reduced to legal and moral rules, inclusive of custom, education, religion, and various forms or sources of law. In this model, markets are not given, they are socially constructed by the interactions of the institutions that form and operate through them. At the very least, markets—and indeed the economic system itself—depend upon the legal foundations of those in control of the state (or those who create the laws of property, contract, tort, etc.) and the strategic behavior of firms and other economic agents.

ECONOMIC THEORY
The conventional assumptions of economic theory, in its static form, have tended to include (1) perfect competition and perfect knowledge (and therefore perfect foresight); (2) given and unchanging technology, resources, tastes, population, and structure of rights; and (3) individual agents that operate independent of each other, that are mobile, and that calculate rationally in order to maximize the satisfaction (or utility) derivable from their real incomes. One or more of these assumptions can be modified, thereby engendering an array of further possibilities, such as a variety of noncompetitive conditions, imperfect information, asymmetrical information, interdependent tastes, changes in the distribution and content of rights, behavior that is less than maximizing, and changes in technology, resources, tastes, and population. Such modifications may or may not add realism, but they do tend to introduce dynamic elements.

The conduct of economics, like that of any intellectual discipline, inevitably involves some type of abstraction, such as the reduction of the number of variables in a model down to the ones deemed most important. This makes the enterprise more manageable. That being the case, economics involves both the study of actual economies and the analysis of conceptual, abstract economies. Closely related is the research protocol stipulating epistemological credentials. At one end of a spectrum is the capacity to produce unique determinate optimal equilibrium results; at the other, to produce an array of possibilities at the conditions governing their realization.

APPROACHES TO ECONOMICS
The history of economics is very much a story of schools of thought. There have been multiple schools of thought, together constituting a heterogeneous discipline, and each school has itself been heterogeneous. This heterogeneity is the result of a combination of a multifaceted economy and different positions or standpoints from which the economy can be studied. There is nothing about the economy or the training of economists that requires that one and only one variable, point of entry, or perspective be used. Accordingly, in every period in the history of the field there has been more than one school of economic thought. A particular school may endeavor to cover the entirety of economics, or it may examine only one or more parts thereof. Economics as a whole is itself further heterogeneous, and because each school typically can be formulated differently, each school is itself heterogeneous. All of this comes under the heading of "theoretical pluralism," which differs from the ontological or paradigmatic pluralism and the epistemological or methodological pluralism described above. And all of these approaches can be rendered further complex and heterogenous by introducing normative premises of one kind or another, such as accepting existing institutions or the status quo distributions of income and wealth.

Theoretical pluralism also takes another form. Every topic in economics is characterized by particular theories. Consider the following: competition, equilibrium, business cycles, income distribution, consumption, supply of
money, commodity demand, capital, investment, the entrepreneur, optimization, money, interest rates, imperialism, economic growth, supply of labor, technology, externalities, incidence of taxation, the origin of the division of labor, and the economic role of government. Each has multiple theories, even multiple groups of theories, that attempt to describe or explain the object of their respective author's attention.

FROM CLASSICALISM TO MARGINALISM

Several questions come to mind when considering why a school of economic thought arises and flowers. The rise of marginal utility economics in the 1870s is a suggestive case in point. "Marginal utility" is the change in utility associated with a change in consumption level. The term also refers to a utilitarian-calculus approach to economic analysis and decision-making. "Classical economics" refers to a group of economic thinkers who wrote after Adam Smith. The school commences with Thomas Robert Malthus, and David Ricardo and also consists of John R. McCoulloch, William Nassau Senior, and James Bill. The approach was largely finished with the work of John Stuart Mill and John Elliott Cairnes.

Among the factors that explain its existence are the following: (1) the deficiencies of classical economics, including its neglect of psychological valuation as an important demand-side aspect of value theory, its focus on economic classes and labor theory (including cost-of-production theory), and its perceived weaknesses as a defense of capitalism; (2) the logical continuation of earlier writings on utility analysis; (3) the growth of static and positivistic theory (laws of the coexistence of variables) challenging Hegelian and other historical theory (the laws of the succession of variables)—or of the study of being rather than becoming; (4) a reaction to Marxism's emphasis on exploitation and the transient character of capitalism as part of an attack on socialist theory in general; and (5) the emergence of academic economics and its tendency to deal with trivia unsuitable for reformers. Academic economics included the use of mathematics, which was attractive insofar as it enabled economics to resemble physics, and because it effectuated a reduction of variables to the neoclassical model of demand and supply.

Among these varied explanations for the rise of the marginal utility approach, one finds ironic incongruities, such as positivism's emphasis on the objective analysis of confirmable materials rather than metaphysical, unconfirmable general theories of history, and the marginal utility school's criticism that classicism's broad conclusions were based on a small structure of knowledge wrapped up in a few theorems. Both of these positions were in conflict with key features of the marginal utility school's subjectivism.

MAINSTREAM ECONOMICS

There has also been a more or less amorphous mainstream of economics, yielding a combination of schools, some more or less orthodox and others more or less heterodox. The mainstream has run from the classical economics of Adam Smith (1723–1790), David Ricardo (1772–1823) and Thomas Robert Malthus (1766–1834), through the early versions of neoclassical economics formulated by Carl Menger (1840–1921) and Alfred Marshall (1842–1924), to the modern formulation by a group led by Paul A. Samuelson (b. 1915). Differences within each school (and between schools) arose along the different axes identified above. These differences were often identified in terms of a school's central problem or focus. The mainstream changed from a grand macroeconomic story of production, growth, and distribution to an equally imposing story of subjectively acting individual economic units and their interaction in markets, along with the resultant allocation of resources. Under the name of "neoclassical economics," the mainstream developed a variety of technical identifications of its central problem, many of them mutually reinforcing, such as the mechanics of utility, the operation of the price system, the working of the free enterprise system, the operation of pure markets, the mechanics of the pure theory of choice, constrained maximization decision making, the allocation of resources, and the mechanics of welfare. Schools of economic thought have tended to define themselves in terms of a central problem; the two most common have been explaining how people make their living and explaining how the economy is organized and controlled. Because the assumptions that characterized the core of mainstream neoclassicism could be changed, a further variety of sub-schools emerged within general neoclassicism. Varieties of theories of noncompetitive conditions, uncertainty, changing tastes, rights, institutions, ideology, technology, and population developed, each offering a more or less distinctively different picture of the economy.

Among the alternatives to the mainstream has been "institutional economics." The central problem here is literally the organization and control of the economy, though with several different foci. One focus was the legal foundations of the economic system; another was the system of cultural beliefs by which people organized and instituted their economic relations, and with which they explained those relations to themselves. Common to both foci was power. The key figures of institutional economics have been Thorstein Veblen (1857–1929), Walton Hamilton (1881–1958), John R. Commons (1862–1945), and John Kenneth Galbraith (1908–2006).
KEYNESIAN ECONOMICS

In the middle third of the twentieth century, nurtured in part by reactions to the Great Depression, the focus of macroeconomics changed from growth in classical terms and the allocation of resources to the determination of the level of income. The key figure of the new macroeconomics was John Maynard Keynes (1883–1946), who argued that classical doctrines to the contrary notwithstanding, the level of income, resulting from factors governing the level of aggregate spending, was not necessarily at the full employment level. This was important not just because variations in spending were involved in the business cycle and in unemployment, but also because so many people depended on employment for their livelihood. In time, Samuelson combined neoclassical microeconomic price and resource-allocation theory with Keynesian macroeconomic income-determination theory to produce the “neo-classical synthesis.”

Thus, in combination with the further differentiating sources outlined above, one could practice economics in numerous different ways. Indeed, it could be argued that neoclassicism, or the neoclassical synthesis, was no longer the undifferentiated hegemon atop the mainstream, and today there are countless variations and combinations of treatments of topics that make up economics. This is true of all of the numerous topics that have had different but useful approaches formulated for them. Macroeconomics, for example, has had a variety of interpretations of what Keynes said and what he intended to say, plus a variety of post-Keynesian theories, not to mention new classical, real, new Keynesian, and other business-cycle theories. Microeconomics has a variety of treatments of how prices and resource allocation are determined; macroeconomics has a variety of treatments of the causes of instability; and both have in common a variety of treatments of uncertainty.

The foregoing does not exhaust the variety of ways in which economists do economics. Some economists study the performance of economic agents as if the agents were engaged in some type of cooperative or noncooperative game. That form of economics was instrumental in developing the strategy of mutual assured destruction (MAD) by the United States and the Soviet Union during the cold war, a strategy which worked to prevent World War III despite its seeming barbarous quality, mainly because the two sides thought more alike than not. Economists who do game theory are among the hordes who practice mathematical economics, a research language and mode of analysis that has been increasingly dominant since the 1960s. Other economists (and psychologists working on economic problems), have enriched the meaning of “rationality” and its attendant motivational attributes. Much of the work of economists is devoted to the description, explanation, and interpretation of what the economy is all about—as should be evident from what has been written above. Many economists self-consciously work at constructing or applying the normative, subjective, and ideological justification for market economies; many others work at its critique. Indeed, it has been said that much of the history of economics has been driven by attempts to influence the distributions of income, wealth, and opportunity in society, as well as by the control and use of government as a political means to economic ends. Which brings this discussion to such combined fields as economic sociology, law and economics, economic anthropology, economic psychology, economic history, and the history of economic thought—fields that are rich in and of themselves.

ECONOMICS, BEHAVIORAL

Underlying behavioral economics and distinguishing it from contemporary (neoclassical) economics is the presumption that the realism of behavioral and institutional
assumptions matter substantively to the modeling of the economic agent (Simon 1959, 1978, 1987). In contemporary economic theory (e.g., Friedman 1953), assumptions are of little analytical consequence as long as the model’s predictions are correct. In behavioral economics, the realism of assumptions affects the accuracy of models’ predictions. It also helps distinguish between spurious correlations and actual cause-and-effect relationships between independent and dependant variables. Even when “as if” neoclassical behavioral assumptions yield correct predictions, if alternative, more realistic assumptions also generate accurate predictions, abiding by the former spaws false and therefore unscientific causal results. However, behavioral economics does not dispute the notion of abstraction and simplicity in model building; it questions models built upon unrealistic simplifying assumptions. When theory and evidence conflict, one includes in one’s search for modeling deficiencies misspecified assumptions, unlike in conventional analysis that focuses largely on missing variables and questioning the validity of the evidence itself (Reder 1982).

Unlike behavioral economics, economic theory typically plays a marginal role in economic psychology. The latter focuses upon applying psychological tools to economic questions and generating evidence that might underlie behavioral assumption of economic agency. It also examines the psychological motivation for economic behavior (Lewis, Webley, and Furnham 1995).

Contemporary behavioral economics is often associated with the contributions of Hebert Simon and, more recently, Daniel Kahneman and Amos Tversky (Kahneman and Tversky 1979; Tversky and Kahneman 1981), all of whom are Nobel Prize Laureates. Thus far, George Katona’s earlier pioneering contributions (1951, 1975) revising the psychological assumptions of consumer behavior in economic theory have gone largely unnoticed. Connected with Simon, Kahneman, Tversky, and their colleagues and associates are the presentation of new theories that either supplement or revise neoclassical micro and macro theories (Altman 2006; Camerer, Lowenstein, and Rabin 2003; Cyert and March 1963; Frank 1988; Shiller 1993; Thaler 1992; Williamson 1975).

Simon introduced the concepts of bounded rationality and satisficing, integrating into economic theory the reality of the cognitive limitations of individuals in terms of computational ability and knowledge acquisition that can only be realized at a cost. Rational individuals adopt behavioral procedures designed to limit such costs that differ descriptively and normatively from the conventional economic standard. Satisficing is the rational alternative to optimizing in a world of bounded rationality. In this case, it is possible for the firm’s output and profit and the individual’s utility to be less than they would be in a world with no limits to human cognitive abilities. Neoclassical norms are no longer optimal or descriptively accurate. Simon also emphasized the importance of recognizing the importance of power relationships, conflicts, fairness, altruism, and institutions for modeling economic agency—variables that are given little space in conventional theory. Individuals might be maximizing their own well-being at the expense of others or society at large; utility might be enhanced at the expense of material wealth (Kahneman, Knetsch, Thaler 1986). Kahneman and Tversky developed prospect theory based on their experiments as an alternative to expected subjective utility theory, where individuals weigh losses more than gains and evaluate their utility in terms of relative positioning. Wealth maximization is not the end game in their descriptive modeling framework. Perspectives developed here have given rise to the revealing ultimatum and dictator game experiments wherein individuals make material sacrifices in the name of fairness (Güth 1995).

Independent of the work of Simon and more contemporary behavioral economists, Harvey Leibenstein (1957, 1966, 1979) developed the concepts of efficiency wages and x-efficiency theory (see Frantz 1997, for details). Based on the evidence, he assumes that effort inputs into the process of production are variable, not fixed at some maximum, as is assumed in conventional theory. Therefore, costs need not be minimized nor output maximized. Effort maximizing remains the ideal for wealth maximization or x-efficiency to be achieved. However, for this to transpire, appropriate market conditions and in-firm incentive environments (often far removed from neoclassical norms) must be developed. The efficiency wage and x-efficiency literature have been extended, for example in Akerlof (2002), Akerlof and Yellen (1986), Altman (1996), Darity and Goldsmith (1996), Stiglitz (1987), and Tomer (1997).

There are roughly two major perspectives within behavioral economics. The one that follows and extends the work of the psychologists Kahneman and Tversky is especially focused on, demonstrating through experiments the extent to which human behavior deviates from neoclassical norms, where the latter are used as the benchmark for economic rationality. By such standards individuals are found to be largely irrational, but such behavior might possibly be corrected through education or government intervention. Irrationality in behavior as the norm is completely inconsistent with conventional theory, and would be regarded as suboptimal in the realm of production and consumption. Such findings are therefore thought to undermine the legitimacy of much contemporary economic modeling. Conventional theory is assumed to provide an adequate description of how individuals behave, and holds that this behavior is also normatively optimal. Many behavioral economists argue that
conventional theory fails as an accurate descriptor of even average human behavior, although it might very well be normatively correct. Vernon Smith (2003, 2005) has challenged many of the empirical findings of such behavioral economists, arguing that the incentive environment of many of their experiments are far removed from what is typically found in the real world of economic life. But Smith and his colleagues have also challenged the modeling assumptions (especially their institutional parameters) of contemporary theory, also using experimental data. Smith finds that human behavior is largely economically rational.

Compatible with Smith’s view on behavioral economics is a perspective that builds on the contributions of Simon. Individuals are assumed to be largely rational and intelligent, developing procedures and institutions that best suit their individual needs given the constraints that they face (March 1978; Smith 2003; Todd and Gigerenzer 2003). This approach to human behavior is sometimes referred to as “ecological rationality.” Deviations from neoclassical norms are therefore not regarded as expressions of irrationality yielding suboptimal socioeconomic outcomes. Neoclassical procedures might very well yield suboptimal outcomes, but errors in decision making can be corrected through evolutionary processes such as learning.

Behavioral economics enriches conventional theory by introducing modeling variables and parameters that make for more scientific causal and predictive analysis. It does not reject the importance of incentives and opportunity costs in decision making, but it does question wealth maximization as dominating the decision-making process, economic efficiency as the end product of individual decision making, and the extent to which neoclassical behavioral norms should serve as appropriate benchmarks for economic analysis (Altman 2005). This in turn opens the door wide open for reconstructing economic theory, engaging institutional analysis as a partner in model building and inviting public policy analysis to help better understand the constraints and incentive environments under which economic agents make boundedly rational choices.

ECONOMICS, CLASSICAL

The term “classical economics” was coined by the German political philosopher and economist Karl Marx, who stated “that by classical Political Economy, I understand that economy which, since the time of W. Petty, has investigated the real relations in bourgeois society” (Marx 1954, p. 85n.). Classical economics included, for example, the physiocrats, the English economist David Ricardo, and partly the Scottish economist Adam Smith; it excluded such authors as Thomas Robert Malthus and Jean-Baptiste Say, whom Marx considered “vulgar economists” dealing with “appearances” only.

Generally, economists and scholars have not adopted Marx’s definition of classical economics. According to other interpreters there was no deep cleavage between earlier and later economists. The continuity thesis was expressed most forcefully by Alfred Marshall around the turn of the eighteenth century and in contemporary times by John R. Hicks and Paul A. Samuelson. Marshall perceived the classical economists as essentially early and somewhat crude demand and supply theorists, with the demand side in its infancy. The received Marshallian interpretation was challenged by Piero Sraffa, first in his introduction to volume I of his edition of Ricardo’s works and correspondence (1951), and secondly in his Production of Commodities by Means of Commodities: Prelude to a Critique of Economic Theory (1960), in which he reformulated the classical approach to the theory of value and distribution and showed that its analytical structure is fundamentally different from later marginalist (or neoclassical) analysis.

METHOD, SCOPE, AND CONTENT

The classical economists were concerned with the laws governing the emerging capitalist economy, characterized by the stratification of society into three classes of workers, landowners, and the rising capitalists; wage labor as the dominant form of the appropriation of other people's capacity to work; an increasingly sophisticated division of labor within and between firms; the coordination of economic activity via a system of interdependent markets in which transactions are mediated through money; and significant technical, organizational, and institutional change. In short, they were concerned with the production, distribution, and use of wealth of an economic system that was incessantly in motion. How should one analyze such a system? The ingenious device of the classical authors for seeing through the complexities of the modern economy consisted of distinguishing between the “actual” or “market” values of the relevant variables—the distributive rates and prices—and their “normal” or “natural” values. The former were taken to reflect all kinds of influences, many of an accidental or temporary nature, about which no general propositions were possible, whereas the latter were seen to express the persistent, nonaccidental, and nontemporary factors governing the economy, which could be systematically studied.

The method of analysis the classical economists adopted is known as the method of long-period positions of the economy. Any such position is one toward which the system is taken to gravitate as the result of the self-seeking actions of agents, thereby putting into sharp relief the fundamental forces at work. In conditions of free competition, that is, the absence of significant barriers to entry or exit from all markets, the resulting long-period position is characterized by a uniform rate of profits (subject, perhaps, to persistent inter-industry differentials reflecting different levels of risk) and uniform rates of

Morris Altman
remuneration for each particular kind of primary input. Competitive conditions were taken to engender cost-minimizing behavior of profit-seeking producers.

The determination of the general rate of profits, the rents of land, and the corresponding system of relative prices constitute the analytical core of classical political economy. It was meant to lay the foundation of all other economic analysis, including the investigation of capital accumulation and technical progress; of development and growth; of social transformation and structural change; and of taxation and public debt. The pivotal role of the theory of value and distribution can be inferred from the fact that the latter is typically developed right at the beginning of major classical works.

**VALUE AND DISTRIBUTION**

The classical concept of production starts from the following interrelated premises. First, human beings cannot create matter, they can only decompose or recompose and move it. Production involves productive consumption, and the real cost of a commodity consists in the commodities necessarily destroyed in the course of its production. This concept of physical real cost, according to Sraffa, differs markedly from later marginalist concepts, with their emphasis on "psychic cost." Second, production consists essentially of a circular flow: Commodities are produced by means of commodities. This idea was advocated by William Petty and Richard Cantillon and was most effectively expressed in François Quesnay’s *Tableau économique* (Aspromourgos, 1996). It is in stark contrast with the "Austrian" view of production as a one-way avenue leading from the services of original factors of production to consumption goods. Third, all property incomes—profits and rents—are explained in terms of the social surplus; that is, those quantities of the different commodities that are left over after the necessary means of production used up and the means of subsistence in the support of workers have been deducted from the gross outputs produced during a year. In this conceptualization, the necessary real wages of labor are considered no less indispensable as inputs and thus "agents of production" (James Mill 1826, p. 165) than raw materials, tools, or machines. Fourth, profits, rents, and relative prices are explained essentially in terms of magnitudes that can, in principle, be observed, measured, or calculated. The objectivist orientation of classical economics has received its perhaps strongest articulation in a famous proclamation by William Petty, who, in his *Political Arithmetic*, published in 1690, stressed that he was to express himself exclusively “in Terms of Number, Weight, or Measure” (Petty 1986, p. 244).

The classical economists proceeded essentially in two steps. In a first step they isolated the main factors that were seen to determine income distribution and the prices supporting that distribution in specified conditions; that is, in a given place and time. The theory of value and distribution was designed to identify in abstracto the dominant factors at work and to analyze their interaction. In a second step, the classical authors turned to an investigation of the causes that, over time, systematically affected the factors at work from within the economic system. This was the realm of the classical analysis of capital accumulation, technical change, economic growth, and socio-economic development.

The rate of profits is the ratio of two bundles of heterogeneous commodities, the social surplus (exclusive of rent), and the social capital. In order to be able to compare these bundles, a theory of value was needed. With a circular flow the values of commodities can only be determined by means of simultaneous equations, a tool not available to the classical economists. They therefore approached the problem of value and distribution in a roundabout way, typically by first identifying an “ultimate measure of value” by means of which heterogeneous commodities were meant to be rendered commensurable. Several authors, including Smith, Ricardo, and Marx, had reached the conclusion that labor was the sought standard and thus arrived at some version of the labor theory of value. This was understandable in view of the unresolved tension between concepts and tools. However, it is far from clear how these labor values could be ascertained in a circular framework except by solving a system of simultaneous equations. In fact, with the benefit of hindsight, contemporary economists know that the labor theory of value landed the classical approach in an impasse and was one of the reasons for its premature abandonment and the rise to dominance of marginalist theory.

Yet, as Sraffa (1960, p. 6) showed, the classical economists were correct in assuming that a coherent determination of the general rate of profits and prices was possible in terms of the two sets of data on which they based their theory of value:

1. the system of production in use, described in terms of the methods of production and productive consumption actually employed; and
2. the real wage rate (or, alternatively, the share of wages).

This can be shown as follows: Let \( T_i, M_f \) and \( F_i \) designate the inputs of three commodities—tools \( (t) \), raw materials \( (m) \), and the food of workers \( (f) \)—employed as means of production and means of subsistence in industry \( i \) \( (i = t, m, f) \), and \( T, M \) and \( F \) the total outputs in the three industries. Denoting the value of one unit of commodity \( i \) by \( p_i \) \( (i = t, m, f) \), one has the following system of price equations:
\[
\begin{align*}
(T_p + M_p + F_p(1 + r) = Tp_t \\
(Tm_p + Mm_p + Fm_p(1 + r) = Mp_m \\
(Tf_p + Mf_p + Ff_p(1 + r) = Fp_f
\end{align*}
\]

Flukes apart, these equations are independent of one another. Fixing a standard of value, for example, \( p_r = 1 \), provides a fourth equation and no additional unknown, so that the system of equations can be solved for the dependent variables: the general rate of profits and prices. The distribution of the surplus must be determined at the same time and in the same way as are the prices of commodities.

**CAPITAL ACCUMULATION AND ECONOMIC DEVELOPMENT**

With the rate of profits determined on the basis of data (1) and (2), the classical authors turned to the problem of the accumulation of capital and thus of the growth of the system. They typically assumed that the process of economic expansion was not constrained by an insufficient supply of labor, because the workforce needed was seen to be created endogenously, either via some population mechanism, as in the case of Malthus, or via the labor-displacing effects of machinery, as in the case of Marx’s “industrial reserve army of the unemployed” (Marx 1977, p. 600). Ricardo discussed both mechanisms and also analyzed the case in which capital accumulates and the population grows, but there is no technical progress. Due to diminishing returns in agriculture, a rise in differential rents paid on intramarginal lands will, for a given real wage rate, entail a falling rate of profit. (The theory of intensive diminishing returns was later taken up by the marginalist economists who thought that the underlying principle could be generalized from agriculture to all industries and to all factors of production [labor, land, and capital] alike and a theory be elaborated in terms of a single principle only: that of relative scarcity.)

The classical authors also discussed different forms of technical progress. In Adam Smith capital accumulation increases the extent of the market and thus allows for an ever-deeper division of labor. This increases labor productivity due to gains of specialization and induced inventions of machinery and thus engenders growing levels of income per capita. Smith’s endogenous growth mechanism is a virtuous circle. Other classical authors were somewhat less optimistic. Ricardo, in the chapter on machinery in the *Principles* (1821) contemplated the case of a kind of mechanization that is gross output reducing: While labor productivity rises, total employment and the output-capital ratio (or maximum rate of profits) fall. This case reappears in Marx’s discussion of the rising organic composition of capital and, given the share of wages, falling tendency of profitability. In 1967 Richard Goodwin formalized some of the classical ideas on accumulation and distribution in terms of an adaptation of the predator-prey model developed in the theory of animal populations.

**TRADE AND MONEY**

The classical economists advocated trade liberalization. According to Smith the specialization pattern of an economy would follow its absolute cost advantages. Via an opening of domestic and foreign markets trade would allow a deeper division of labor and thus enhance productivity growth. Ricardo showed, contrary to Smith, that what really mattered were comparative advantages and not absolute ones. Assume that one of two economies is able to produce all commodities at lower unit costs. Only this economy would export and the other one import. This would, however, engender a specie-flow mechanism with prices in the former economy rising and in the latter one falling. Ricardo’s theory of money, a version of the quantity theory, was an integral part of his trade theory. Sooner or later some prices in the latter economy would have fallen below the levels in the first one and thereby reverse the competitive situation. This would relate precisely to those commodities in the production of which the second economy has a comparative advantage.

Since the publication of Sraffa’s *Production of Commodities by Means of Commodities* there has been a revival of the classical approach. For a summary account of what has been achieved, see, for example, the work of Heinz D. Kurz and Neri Salvadori.

Economics, Experimental

For generations economics was a nonlaboratory science. Economists could construct theories and analyze naturally occurring data, but the luxuries of control and replication were elusive. The discipline of experimental economics has challenged and changed this perception. Experimental economics provides for a variety of modes of scientific inquiry through the creation of small-scale but real laboratory economic systems. Most experimental economics research has dealt with microeconomic problems, but there is a growing body of work with a more macroeconomic flavor.

Experimental economics got its start in the 1950s and was fully credentialed when Vernon L. Smith was awarded half of the 2002 Nobel Prize in Economic Science. In the Nobel citation Smith is recognized as the father of experimental economics, in the sense that he “made the most important early contributions, but he also remains a key figure in the field to date.” However, as with any scientific advance, there are other pioneering streams that feed into the final river. One universally recognized starting point for experimental economics was the effort by Harvard economist Edward H. Chamberlin (1866–1967) to demonstrate to his students the poor predictive theory of perfectly competitive market models. Chamberlin assigned each student a hypothetical “cost” or “value” and encouraged them to make profitable trades through a random meeting process. Chamberlin’s major insight was to argue that if the hypothetical costs and values were valid representations, then supply and demand curves could be computed for the minieconomy. Chamberlin’s result was that the markets failed to converge to the perfectly competitive predictions.

A few years later Smith, a young Harvard Ph.D. then on the faculty at Purdue, decided to try an exercise similar to Chamberlin’s, but with some critical changes. First, Smith conducted the markets with an institution, the double oral auction, which is an analog of the trading process on the New York Stock Exchange. The double auction has information and price progression features different from the Chamberlin exercise. Second, the markets were repeated. Third (and somewhat later), the individual costs and values were made salient by making real payments to the market participants. Under these conditions the markets converged robustly to the competitive outcomes. The Journal of Political Economy published Smith’s results in 1962, and experimental economics as it is most widely known today was born. Smith published his major methodology treatise on experimental economics in 1982. As delineated by Smith, the elements of an induced economic environment (essentially the conditions of supply and demand) and of a carefully defined economic institution are the core of any economics experiment. This holds true even when the institutions look less like regular markets and more like voting rules or bargaining processes (Fiorina and Plott 1978). Paired with this, the 1982 article also discussed experimental design conditions sufficient to produce a valid, controlled economics experiment.

Heinz D. Kurz
Meanwhile, at about the same time as Smith’s earliest work, others were making seminal contributions. James W. Friedman (1967), Lawrence E. Fouraker and Sidney Siegel (1963), and Heinz Sauermann and Reinhard Selten (1959) were similarly pioneering, although all were more oriented toward oligopoly and bargaining. Selten in particular continued to pursue experimental research and was a Nobel laureate for his theoretical contributions in the first game theory year of 1994.

When Smith visited the California Institute of Technology (Caltech) in the late 1970s, he met a former Purdue colleague on the Caltech faculty, Charles R. Plott, who had also become a fan of experimental methodology. Smith and Plott began a highly productive collaboration, and Plott also staked out crucial methodological advances for using experimental economics in regulatory and public policy analyses. For example, when the government proposed altering the way that the pricing of inland barge transportation was regulated, Plott and James T. Hong (1982) used experimental markets to evaluate the change. Experimental economics has been used as an evaluative public policy tool in areas as disparate as airport “slot” auctions, markets for pollution permits, water auctions, and antitrust issues. Another 1970s’ stream of experimental economics was the work at Texas A&M of Raymond C. Battalio and John H. Kagel (often with Leonard Green 1981) in designing small experimental economics environments for animal economies.

The growth in the number of experimental researchers naturally led to the organization of professional societies; for example, in Germany there is the Society for Experimental Economics Research, and in the United States there is the Economic Science Association. Both sponsor activities with a worldwide audience. A basic undergraduate textbook in the area is available from Douglas D. Davis and Charles A. Holt (1993).

ECONOMICS, INSTITUTIONAL

Institutional economists are the leading American heterodox school of economics. They differ from the orthodox neoclassical mainstream in their emphasis on the manmade institutions that help form and operate through the markets created by the institutions. They study individual institutions, culture, actual economies and their institutional foundations, and the mutual impacts of private and public sectors, the domain sometimes called the legal-economic nexus. Neoclassicists tend to emphasize an abstract, idealized economic system and the play of market forces. Institutionalists treat government as important and ubiquitous, like it or not—as part of, rather than exogenous to, the economic system.

Institutionalists seek to develop a body of empirical and theoretical knowledge of the organization, control, operation, and evolution of the economic system, particularly the institutions that produce, together with individual choices, the allocation of resources and the distribution of income. Institutionalists have produced a critique of capitalism and of neoclassicism as its expression and rationalization. Relatively few institutionalists oppose capitalism, but most distinguish between capitalism and a market economy. Many are sympathetic to the evolution of the economic system along lines giving increased effect to the interests of workers. Some call for conscious, activist government planning of varying types, but most seek a truly more competitive economy, a government not dominated by business interests, and laws not catering to the interests of business and upper-income classes.

John Maurice Clark (1884–1963), Robert Lee Hale (1884–1969), and Richard Ely (1854–1943). Veblen's satiric critique of business and consumerism under capitalism—not least his emphasis on status emulation and conspicuous consumption—helped both the other institutionalists and most economists. All members of the school stressed the allocative and distributional importance of actual institutions. Some, like Mitchell, pioneered the empirical and theoretical study of business cycles in an economy dominated by high finance and a pecuniary culture. Most if not all institutionalists pursued the analysis of the economy as both a cultural system and a system of power. Some followed Commons's complex analysis of the legal foundations of capitalism and studied empirically and theoretically the legal-economic nexus.

Differences of emphasis and interpretation have rendered institutionalism as heterogeneous as any other school of economics. Some institutionalists have been conservative, most quite liberal. In addition to planning versus competition, other conflicts have developed between the followers of Clarence Edwin Ayres (1891–1972) and of John R. Commons over the theory of value appropriate for institutional economics, and the relative importance of deliberative and nondeliberative decision making. All agree, however, that the principal determinant of resource allocation is institutions and not the pure abstract market. Other topics commonly agreed upon as important are evolution, behavior, power, stratification, agency, the creation and structuring of markets, the legal-economic nexus, the role of culture and belief systems, and the corporate system.

The Canadian-born American economist John Kenneth Galbraith (1908–2006) has been for some time the most prominent institutionalist. Institutionalism as a whole has a complex existence: Institutionalists contribute to most fields in economics but tend to be marginalized by the mainstream. Most institutionalists accept, however reluctantly, their heterodox status, and they work hard to improve their position in the world. Several journals are institutionalist in orientation. Institutionalism has developed strongly in Europe.

ECONOMICS, INTERNATIONAL

International economics is a standard, and perhaps the oldest, field discipline within economics. This discipline involves an analysis of all economic aspects of an international nature, aspects that coincide with the existence of multiple countries and to some extent separated economies. In a historical coincidence, parts of international economics that developed prior to general micro- or macroeconomics deal in a peculiar way with essentially the same phenomena as general economic theory.

International economics addresses such issues as international trade, movements of factors of production between countries, exchange rates, open-economy macroeconomic policy, international monetary institutions, and globalization. All these issues relate to the so-called open economy, a term economists use for an economy of a country that is to some extent separated from the rest of the world (politically, monetarily, or otherwise) but at the same time has economic ties to it. These ties manifest themselves on one hand as flows of physical goods or factors of production and their services, or on the other as flows of money or its substitutes. For broad classification, then, it is possible to divide international economics into two areas of study: international trade and international finance.

INTERNATIONAL TRADE THEORY

Probably the most prominent position within international economics is enjoyed by international trade theory, which seeks to identify the gains from trade between countries; the factors that determine the pattern of specialization; the volume of trade and the terms of trade (i.e., prices); the impact of trade on income distribution; and the impact of the barriers to trade on all of the above. From a practical point of view, however, its goal has always been, as the international economist Edward Leamer remarked, to answer one single question of paramount importance: when, if ever, is it beneficial to put obstacles to the flow of goods between countries?

It is precisely this question that gave rise to early economic speculations and philosophizing, and in that sense international trade theory was an indispensable part of political economy (and later economics) from the very beginning. All the scholars who can be considered among the founding fathers of economics—Richard Cantillon (1680–1734), David Hume (1711–1776), Adam Smith (1723–1790), and David Ricardo (1772–1823)—explicitly addressed this question, and for the most part part their answer was negative. The work of these early economists formed the basis of what would be known as the free-trade doctrine and provided the intellectual foundation for the free-trade movement in the nineteenth century. These
The authors showed that many of the apprehensions surrounding foreign trade (trade deficits and crises) were based on myth.

The theory of comparative advantage made a major contribution to the theory of international trade (and later to general microeconomics). This theory, attributable to Robert Torrens (1780–1864), James Mill (1773–1836), and Ricardo, demonstrated that two countries can engage in trade even when one of the countries can produce all goods more cheaply (because of greater productivity or lower nominal cost).

Although the theory of comparative advantage understood trade to be based on differences in productivity, later theories enriched the perspective by pointing to two other sources of trade. First, trade can also result from differences in resource endowments; in other words, countries can specialize in, and export, products made from resources that are plentiful in that country. This has come to be known as the Heckscher-Ohlin theorem (which became the basis of the Heckscher-Ohlin-Samuelson model, after its authors, Eli Heckscher, Bertil Ohlin, and Paul Samuelson). Second, the source of trade can be the consumers themselves: the difference in their preference. Before this model was developed, much of the trade flows between countries seemed puzzling, as they consist of similar types of products (so-called intra-industry trade), rather than dissimilar products as the theory based on differences in productivity or resource endowment would predict.

Besides sources of trade, international trade theory focuses on the consequences of trade for prices of factors of production, and explains the tendency of trade to bring about their equalization across countries (which became known as the Factor Price Equalization Theorem, developed, independently, by Abba Lerner and Samuelson). Further development of international trade theory incorporated the effects of the economies of scale and market structure (imperfect competition) on all aspects of trade. A special part of the theory is concerned with the alternative to international movements of goods: the movement of labor and capital across borders.

During the twentieth century, the answers offered by international trade theory developed greater precision. Although the theory, as it became increasingly refined, made some theoretical qualifications of the conditions under which free trade is the first best policy, the practical presumption in favor of free-trade policy remains largely unchallenged. Indeed, in opinion surveys of economists the statement “trade barriers reduce general economic welfare” typically draws the greatest consensus.

**INTERNATIONAL FINANCE**

A corollary to flows of tangible goods, services, and factors of production are financial flows. The openness of an economy, and the existence of “the rest of the world,” adds several new dimensions to the discussion of such macroeconomic topics as national product, price level, interest rates, and their interrelations, and government policies aimed at their management. Only the international context gives rise to such frequently discussed issues as balance of payments, exchange rates, international monetary institutions, international aid, borrowing, and indebtedness.

**Balance of Payments** Balance of payments refers to the financial flows between the given economy on one hand and the rest of the world on the other. Understanding the logic of the balance of payments and knowing the determinants and consequences of its various subcomponents, although not a policy goal in itself, is helpful in setting policy goals and formulating policy measures.

**Exchange Rate** The exchange rate, the value of domestic currency with respect to foreign currencies, has a major influence on the balance of payments. The theory of how the exchange rate is determined is therefore central to this part of international economics, which examines the role of export and import demands, differences in interest rates, and expected inflation across countries. One theory, the interest rate parity, points out certain necessary relations between the expected changes in the exchange rate and countries’ interest rate differentials. As the rate of return on assets in each country must be equal, lower interest rates in one country as compared to the other will be seen as justifiable only if the currency of this country is expected to gain in value with respect to the currency of the other country. If this were not so, one of the currencies would be seen as more attractive by investors, and their attempt to exploit this opportunity would bring the real rates of return ultimately to equality.

Another theory of exchange rate determination, the theory of Purchasing Power Parity (PPP), stipulates that the exchange rate tends to correspond to the ratio of price levels in the two respective countries (or, in its modern version, that changes in exchange rate correspond to changes in the price level ratios, i.e., inflation rates). If this were not so, prices in the one country would be generally lower than in the other, which would make buying in the first more attractive than in the second. Greater demand for currency of the first country compared to that of the second would cause its value (i.e., its exchange rate) to appreciate, which would tend to eliminate the difference in the attractiveness of buying in the two countries. Only when the exchange rate will equal the ratio of the price levels will there be no difference between the countries, and no tendency for change.

Exchange rates, in their relation to the balance of payments, are also linked to the open-economy output deter-
mination. They are related to the national product through two channels. First, the exchange rate is decisive in determining the amount of production demanded by, and thus produced for, buyers in foreign countries. The less valuable the domestic currency vis-à-vis the foreign one, the higher the output the country tends to generate. Second, through the asset market, any level of product corresponds to a particular interest rate, and the interest rate in turn is important in determining the exchange rate. The higher the output, the higher the interest rate and the more valuable the domestic currency. Thus there is likely to be one particular level of exchange rate compatible with a given level of output.

Given the importance of exchange rates as a factor in open-economy macroeconomics, it is no wonder that exchange rates are subject to different degrees of government attention. A country's policy may vary from nonintervention (a “floating” currency) to a fixed exchange rate (a currency “peg”). In the latter case, a government, typically through its central bank, attempts to keep the exchange rate within certain limits. Besides the standard tools of monetary policy (influencing domestic money supply), this is generally achieved through foreign exchange interventions. These are purchases or sales of foreign exchange currency for domestic currency through which the value of domestic currency is decreased (if foreign currency is purchased) or increased (if foreign currency is sold). The feasibility of such management is limited, on one hand by the danger of inflation (if too much domestic currency is swapped for foreign currency), and on the other by limited supplies of foreign currency (a central bank can boost the value of its currency only as long as it has foreign currency at its disposal). Special fixed-rate monetary and exchange rate regimes would include two somewhat similar arrangements: the gold standard and a currency board. The former—historically prevalent internationally but now abandoned for not entirely economic reasons—consists of defining the monetary units of currencies in terms of gold. The currency board, a relatively recent though still not very common phenomenon, replaces gold metal in a currency definition with a foreign exchange. If domestic currency becomes defined as a particular amount of gold or a particular number of units of foreign currency, both money supply and the exchange rate are determined.

If market forces are suppressed altogether and domestic currency cannot be freely exchanged for the foreign one (as assumed so far), the domestic currency is considered nonconvertible. In such cases, the official exchange rate becomes a matter of government fiat and decree, although it is likely to coexist with a much different exchange rate that is likely to develop on a black market.

The policy choice regarding the exchange rate regime has important repercussions for macroeconomic policy. Floating exchange rates allow for greater autonomy in monetary policy and provide insulation from outside monetary shocks and an automatic mechanism for maintaining external balance. This comes, however, at a cost of greater uncertainty about its level and the lack of any disciplining factor for domestic monetary authority. Yet, at the beginning of the twenty-first century, floating exchange rates seem to have prevailed. In an open economy, it is generally considered unfeasible to maintain fixed exchange rates while insisting on autonomous policy.

In some sense, the heritage of fixed exchange rates survives in the theory of optimum currency areas (developed by Robert Mundell). For the countries involved, fixed exchange rates have the same effect on (in)dependence of monetary policy as would the common currency. And just as fixed exchange rates are not always feasible, neither can common currency always be thought of as an improvement. The theory of optimum currency areas recognizes both benefits (lower transaction cost) and costs (loss of policy autonomy and openness to shocks) of monetary integration, and thus makes clear under what conditions such integration is beneficial.

In today's globalized world economy, international economics stands only to gain in importance. However, as borders between countries become increasingly irrelevant and their policies harmonized, international economics may become indistinguishable from conventional economics. After all, if the world were one country, the difference between international and domestic would disappear altogether.

Economics, Islamic

ECONOMICS, ISLAMIC

As part of the Islamization of Knowledge agenda, Islamic economics as a discipline was formally laid down in the First International Conference on Islamic Economics in 1976. The objective was to present the case of Islamic economics (IE) in a language common to financiers, politicians, and economists. Deriving its inspiration from the ideals of Islam, IE studies the interaction of the spiritual and material paradigm, with the ultimate aim of establishing a just and fair socioeconomic system.

The biggest challenge faced by IE has been, and still is, to reconcile the material self-interest with the “etho-religious” or moral self-interest of agents and the welfare of society as a whole, and to replace interest-based financial institutions with interest-free institutions guided by Shariah, Islamic law, and moral standards. The compatibility between Islam and capitalism is studied by Maxime Rodinson in his book *Islam and Capitalism* (1966). In his work on the textual analysis of Qur’an and other Islamic knowledge sources and the economic history of the Islamic world, Rodinson demonstrates that Muslims never had any trouble reconciling the money-making mechanism under the Islamic framework. In contrast, Bryan S. Turner in *Weber and Islam: A Critical Study* (1974) argues that, for Max Weber, “it was the patrimonial nature of Muslim political institutions which precluded the emergence of capitalist preconditions, namely rational law, a free labor market, autonomous cities, a money economy and a bourgeois class” (Turner [1974] 1998, p. 2). Thus, Turner does not ultimately subscribe to Weber’s view of Islam. While posing a different critique from Rodinson’s, Turner ascribes a combination of Puritanism and orientalism to Weber that skews the latter’s view of the relationship between Islam and capitalist development. However, the process of reconciliation between IE and other economic systems needs to emerge by implementing just socioeconomic paradigm (Chapra 2003).

IE seeks to devise ways in which economic agents and markets can be directed by moral and social values based on Shariah. Its supporters believe that all economic and business activities should be based on an ethoreligious paradigm, with the sole aim being the welfare of individuals and society as a whole. In many ways, it pursues the same objective as conventional economics, but within religious-based moral codes of Islam.

According to IE, moral codes and principles should regulate economic activities to ensure the elimination of poverty and glaring inequalities in the distribution of wealth and resources. The state should take responsibility for those objectives and utilize Islamic fiscal tools such as *zakat* (the annual 2.5% voluntary tithe to the needy), taxation, equity, loss-profit, and risk sharing to achieve them. Factors of production should be treated on an equity basis, and no predetermined return on capital is allowed. These are the core features of Islamic economics, and are what make it different from its conventional counterpart.

IE provides the means for the material and spiritual growth and welfare of the human race. It reflects the physical and spiritual aspects of life, holding them in a balance so that they supplement and reinforce each other, and if any clash does occur, moral and ethical values reign supreme. Religiously based moral checks on economic and market activities are set up to ensure the true success of both individuals and society. Activities that are in conflict with Islamic spiritual, social, and moral values are prohibited in Islamic economics.

Both the literature on IE and the number of financial institutions based on Islamic principles have increased rapidly in recent years. Many economics journals are allocating space for Islamic economics and finance, and there are some that are dedicated especially to the publication of articles related to Islamic economics and finance, including the *International Journal of Islamic Economics* (London), the *Journal of Islamic Economics* (Jeddah), and the *Islamic Development Bank Journal*. Islamic economics, especially Islamic banking and finance, is taught at universities around the world, including International Islamic University (Malaysia), International Islamic University (Pakistan), the International Centre for Education in Islamic Finance (Malaysia), the London School of Economics, Harvard University, University of Cairo, Monash University, University of Tehran, and numerous universities in Kuwait, United Arab Emirates, Sudan, Malaysia, Indonesia, and Saudi Arabia. Nevertheless, Islamic economics is still a nascent discipline, and a lot of work is being done to put theoretical, empirical, and applied proofs to its claims.

ECONOMICS, KEYNESIAN

Keynesian economics is the approach to macroeconomics that grew out of John Maynard Keynes’s work, especially his *The General Theory of Employment, Interest and Money* (1936) written during the Great Depression. Since Keynes’s work has been interpreted in different ways and inspired various formulations of macroeconomics, it is defined in a number of different ways, including the approach to macroeconomics in which: aggregate demand plays a major role in determining output and employment; involuntary unemployment can persist; and fiscal and monetary policy can affect the level of output and employment. Keynes himself recognized that he had a number of predecessors, and it has been suggested that major elements of his approach were anticipated by others (most notably, Michal Kalecki).

In *The General Theory* Keynes argued that employment is determined by the aggregate demand for goods, which is in turn determined (in a closed economy) by consumption demand and investment demand. Consumption depends mainly on the level of real income while investment demand depends on the interest rate, which is determined by money supply and the demand for money, and by business expectations. Given expectations and monetary conditions, employment is determined so that output produced is equal to aggregate demand. The level of employment thus determined may be less than the full employment level at which the supply and demand for labor (which depend on the real wage) become equal. He also examined the aggregate supply side of the economy with a given money wage, and a production function relating output to employment, which determined the average price level. Keynes argued that the wages are likely to be rigid downward when unemployment exists because of the concern of workers with their wage relative to that of others: however, even if wages (and hence the price level) fall, it is unlikely to increase the level of aggregate demand in the face of uncertainty and the negative effect of falling prices on the demand for goods by debtors. Keynes therefore recommended expansionary monetary and especially fiscal policy to increase the level of aggregate demand, employment, and output to reduce unemployment.

Keynes’s analysis is most simply depicted with the income-expenditure model of Figure 1, in which the axes measure income and output, $Y$, and expenditures or demand, $E$. The line marked $C$ is the consumption function that shows the relation between consumption and real income, and the line marked $C + I + G$ is aggregate demand that adds (planned) investment, $I$, and government expenditure, $G$, both assumed to be exogenously given, to it. Equilibrium output, $Y_E$, is determined where the aggregate expenditure line intersects the 45° line so that output equals expenditure. The level of output determines employment, which may imply unemployment. Fiscal and monetary expansion, by increasing $G$ or $I$, can increase output and reduce employment.

Economists such as John Hicks and Franco Modigliani, who were persuaded by Keynes’s theory, tried to relate it to pre-Keynesian neoclassical macroeconomic theory in which the economy was generally thought to be at full employment. A series of models, including the IS-LM and later the aggregate demand–aggregate supply (AD-AS) models, were developed to produce what has come to be called the neoclassical synthesis approach to Keynesian economics. This approach, which uses different types of demand and supply curves and equilibrium condition as in neoclassical theory, implies that unemployment can exist, due to wage rigidity, in the short run, but in the medium and long runs, in which the wage is flexible, the economy is at full employment. When unemployment exists, over the medium and longer runs the money wage falls, which reduces the costs of firms and hence the price level, which reduces the nominal demand for money. The resulting excess supply of money is used to increase spending on goods (by what is called the real balance effect), or is lent out, implying a fall in the interest rate and a rise in investment (and possibly consumption) demand. This increase in aggregate demand increases out-

Economics, Keynesian

put and employment and takes the economy to full employment. With rigid wages in the short run, however, this mechanism does not work itself out, and unemployment can exist. Expansionary fiscal and monetary policy can increase output in the short run, but only increases the price level in the medium and long runs when the economy is at full employment.

In the 1960s, after most advanced countries experienced low unemployment for long periods (arguably due to the success of Keynesian macroeconomic policies), and inflationary pressures began to mount, alternative approaches to macroeconomics began to emerge. Three of them adopted positions opposed to Keynesian economics and can be briefly discussed to show what it is not. The first, monetarist, approach developed by Milton Friedman in 1968 and others returned to the pre-Keynesian idea of flexible wages in the short run, so that full employment always prevails, but allows changes in aggregate demand to affect the level of output and employment, because of misperceptions about the effects of aggregate demand changes, to make it consistent with the facts regarding business cycles. For instance, when money supply increases, workers find their money wage to be higher, but by not taking into account that the price of goods is higher too, they supply more labor, which leads to an increase in output. In the longer run, as workers revise their price expectation, this expansionary effect disappears. According to this approach, although full employment always prevails due to the flexibility of wages, macro policy has a temporary effect on real variables due to the misperceptions of the workers. The second also maintains the assumption of flexible, labor-market clearing wages, but assumes that economic agents do not make systematic expectational errors as they do in the earlier monetarist approach, and assumes rational expectations. This new classical approach developed by Robert Lucas in 1983 and others points out that with agents having rational expectations in the sense that they use all relevant information about the economy to calculate price expectations, fiscal and monetary policy (apart from tax policy changes that affect the supply of labor) are not effective even in the short run, unless the policies’ changes are random and hence unanticipated. The third approach, called the real business cycle approach, continues in this tradition, but explains business cycle fluctuations in terms of technology shocks that affect investment demand and the interest rate and bring about the intertemporal substitution of labor to explain changes in employment.

In addition to real-world phenomena mentioned earlier, Keynesian economics lost ground to these new classical approaches because of its alleged problem in providing proper microfoundations to macroeconomics. The neoclassical synthesis Keynesian approach explained unemployment in terms of wage rigidity, but did not relate the analysis to optimizing microfoundations. The new Keynesian approach tries to develop Keynesian economics to address this problem. An early branch of this approach merely introduced fixed prices and wages into the standard micro-founded general equilibrium model, examining disequilibrium situations in which actual transactions occurred at the “short” side of the market and the effects of such deviations from market clearing in one market spilled over into other markets. Another branch of the approach responded directly to the monetarist and rational expectations approaches, introducing wage price stickiness (such as staggered or sticky wage adjustment) into models with rational expectations to show that it is complete wage flexibility, rather than the assumption about expectations, that produced the policy ineffectiveness result. A final, and most popular new Keynesian branch, provided optimizing microfoundations to wage, price, and interest rate rigidity. Efficiency wages (which prevent the wage from falling when unemployment exists because of its adverse effect on labor efficiency) and wage bargaining, imperfect competition and the “menu” costs of price changes, and asymmetric information in credit markets have been used to explain these rigidities. Some models, such as those that distinguish the role of insiders and outsiders in the wage determination process, imply that aggregate demand changes can have long-term effects on output due to what are called hysteresis effects. While some new Keynesian models imply involuntary unemployment in equilibrium, others do not, but imply only that aggregate demand policies can have effects on output.

The central feature of both the neoclassical synthesis and new Keynesian approach is the rigidity of wages and prices. While wage rigidity is an important element of Keynes’s theory, we have seen that according to Keynes the wage flexibility is no guarantee for full employment. The fact that flexible wages may exacerbate rather than solve unemployment problems has been stressed by another approach to Keynesian economics, called the post-Keynesian approach, which emphasizes the implications of decision-making under uncertainty, monetary institutions, and the effect of income distribution on aggregate demand. According to this approach when the wage and price falls due to the existence of unemployment, the interest rate and real balance effects need not work to increase aggregate demand because an excess supply of money may just lead to a fall in money supply as loans are repaid in a credit money economy with no further effects on the interest rate, because even if the interest rate falls asset holders may wish to hold more money and firms unwilling to increase investment in an uncertain environment, and because falling real wages redistribute income from workers to profit recipients who save a larger proportion of their income. Greater wage flexibility also tends to increase uncertainty in the economy given the importance of wages.
for both firm costs and profits and household income. These ideas add to Keynes's own discussion on the implications of wage flexibility, and are also corroborated by some optimizing models with a new Keynesian flavor.

Keynesian economics has generally been thought to be valid for short-run macroeconomics, but ignored in the analysis of long-run growth analysis. However, if wage flexibility does not automatically take the economy to full employment or at least the natural level of output consistent with price stability, and governments are unwilling or unable to do the same over the medium run, and if technology responds to aggregate demand and output, Keynesian economics may be relevant for the longer run as well. Post-Keynesians and other heterodox economists have, in fact, followed Joan Robinson and others in applying Keynesian economics to the study of long-run growth.

ECONOMICS, LABOR

The field of labor economics is involved with the study of the labor market, including the determinants of employment, unemployment, and wages. The labor market developed as societies moved from feudal to capitalist processes. The development of capitalism in turn led to powerful capitalist owners and an industrial workforce that was concentrated in factories. Conditions of work became, by present Western standards, dirty, demanding, and dangerous. As a result, workers organized unions and began to demand better pay and working conditions, and they set up political organizations like the Labour Party in the United Kingdom. Over the years, organized labor managed to achieve many of their goals, as legislation was introduced in many countries to provide minimum wages, poverty relief, unemployment benefits, and pensions, and to ensure safe working conditions.

The labor market consists of employers, workers, and a government that provides an institutional and legal framework. The distinctive features of labor as a commodity are: (1) except for a slave society, people can only buy and sell labor services; (2) the quality of the labor services provided depends not only on the innate ability of the workers but also on their attitudes to work, to their fellow workers, and to their employers; (3) most employment contracts last for a fairly long time, so there are not frequent repeat purchases of this “commodity”; (4) there is asymmetric information in the labor market about the “quality” of labor services; and, (5) there is an unequal power relationship in the labor market.

Labor markets are different from other markets. As Arthur Okun points out in Prices and Quantities (1981), they are not auction markets that clear instantaneously, but are influenced by “custom and practice.” For example, firing is usually based on last in, first out, and seniority is often given special privileges. There are many interrelated labor markets, differentiated by geography, occupation, industry, and often by gender and race. Analyses of segmented labor markets (primary and secondary markets) provide an interesting window into the role of “power” in labor markets, as demonstrated in the work of Peter Doeringer and Michael Piore (1971). Robert Solow, meanwhile, has emphasized the idea that the labor market is a social institution, and that it is therefore important to consider issues of equity and fairness in labor markets (1990). The labor market is different from other markets because the commodity being traded (labor) is capable of reasoned thought. Hence, the way employers treat workers, and the way other workers treat each other, influences their behavior and productivity, as well as wages.

Labor economics was once an interdisciplinary (institutionalist) study that included historical analysis, industrial relations, sociology, and political science. In the early literature, Adam Smith, David Ricardo, and Karl Marx employed versions of the labor theory of value, which states that the determinant of the value of a commodity is
the amount of labor embodied in it. Marx pointed to the “exploitation” of labor, believing that workers produced “surplus value.” Subsequently, at some point in the post-World War II era, labor economics became a narrow economics subdiscipline in terms of methodology that used neoclassical economic theory (assumptions of maximizing behavior in atomistic, mainly, competitive markets) to analyze various aspects of the labor market, including aspects of employment, unemployment, wages, gender and race discrimination, and immigration. It expanded its boundaries in terms of subject matter, exploring areas of demography, crime, health, marriage, and social relationships (“economics imperialism”) under the guidance of the Nobel Prize-winning economist Gary Becker.

Econometric methods have been used on time-series, cross-section, and panel or longitudinal data to study labor economics and the evaluation of government policies on the labor market. Thus, under the influence of another Nobel Prize-winning economist, George Akerlof, modern labor economics has moved full circle—it now studies labor markets in an interdisciplinary framework (although with formal economic models) that includes concepts of psychology, anthropology, industrial relations, and management theory. Modern labor economics has developed new econometric methods to analyze social safety policies by using controlled experiments, “matching” techniques, and panel estimation techniques with fixed and random effects. Since the mid-1990s, labor economics has embraced “experimental economics” methods devised by innovative economists such as Ernst Fehr and Simon Gächter (2000). In these studies, the concepts of fairness, reciprocity, and equity in the labor market are investigated.

The Great Depression of the 1930s led to studies of unemployment, including long-term unemployment, the impact of unemployment on society, and human degradation caused by unemployment. Much work was done to explain the massive rise of unemployment in terms of “rigid wages” (classical economics), and of inadequate aggregate demand (Keynesian economics). The big increase in unemployment following the “oil shocks” of the 1970s led to theories of “stagflation.” Subsequently, explanations of unemployment pointed to imperfectly functioning markets, with regulated labor market institutions being blamed. Theories then moved on to using concepts of search in a labor market with imperfect information, as described by Edmund Phelps (1970) and Dale Mortenson and Christopher Pissarides (1999). In these models workers are looking for a job when they receive wage offers which follow a normal distribution; some are good and some are bad. They have to decide whether to accept the offer or reject it. If they reject the offer, they are unable to return to it if the subsequent offers are worse.

The post-1960s literature on labor economics moved from macroeconomic analyses of labor markets and industry-level studies to the study of microeconomics (on a firm and individual/household level) of the demand and supply of labor. The development of the human capital approach to analyzing the investments of rational maximizing individuals in education and skills, as outlined by Gary Becker in Human Capital (1964), led to a better understanding of labor supply. Given that investment in human capital is irreversible, work done in the 1990s treated the acquisition of skills as an “investment option” under uncertainty.

The growth of computer usage, and the subsequent development of large data sets, has led to an explosion of econometric analyses. Most of the research to explain wage rates (or earnings) has used earnings functions. Thus, the logarithm of wages (earnings) was explained by human capital, work experience, and various other control variables. Although most studies have found human capital variables to be significant, the explanatory power of these equations is very low. Yet the role of human capital in explaining economic growth has had important policy implications. Minimum wage policies have been analyzed to see if they have helped the poor and led to a fall in employment. David Card and Alan Krueger’s 1995 critical analysis of the data for the United States suggested that minimum wages had little impact on unemployment. This conclusion led to a huge controversy that has continued into the early twenty-first century. The re-introduction of minimum wages in the United Kingdom in 1998 was found by Alan Manning (using monopsonistic models in 2003) to have had no significant impact on employment.
There have been significant advances in the study of the determinants of labor supply and demand using modern econometric techniques and panel data. In studies of labor supply, individuals are assumed to maximize lifetime utility, subject to given budget and time constraints, where they choose an optimal amount of education, work, and leisure. Tax and welfare policies are studied in this framework and have important implications for the policy analysis of negative income taxes and social security benefits. Labor demand is studied for firms that maximize present values of profits by choosing optimal amounts of labor. Labor is treated by firms as a “quasi-fixed” input, according to Walter Oi (1962), and it is analogous to investing in physical capital goods. Advanced studies suggest that firms choose wages to maximize the efficiency of labor (Akerlof and Yellen 1986), or else choose an appropriate sequence of wages to maximize present values (Lazear 1995).

Labor economics has made significant theoretical and empirical strides in understanding the workings of labor markets. Econometric analyses of various tax, welfare, and active labor-market policies have helped to develop new policies for improving the functioning of the labor market and helping the unemployed and the poorer segments of society. However, there is still much work to be done to truly understand the nature of unemployment and poverty.

**ECONOMICS, MARXIAN**

The term *Marxian economics* refers to economic theory inspired by the work of Karl Marx (1818–1883). The salient feature of this research program is the idea that all societies in order to reproduce themselves require labor that will be used to produce the material requirements of reproduction. In all societies, a particular social class performs more work than that required for its own reproduction and the excess labor is appropriated by the dominant classes through property relations, traditions, the legal sys-
Economics, Marxian

tem, and also force. Such exploitative relations are quite transparent in precapitalist modes of production (e.g., slavery and feudalism), whereas in capitalism they are embedded in monetary transactions that give the impression of equal and therefore fair exchanges. Marx was the first to argue that in capitalism workers are exploited not because they are not paid their full wage, but because with the full wage they receive workers are able to pay only for the basket of goods required for the reproduction of their capacity to work (their labor power), which is acquired through what is only a portion of their total labor time. The difference between total labor time and that required to reproduce the workers’ capacity to work is called surplus labor time and its monetary expression, the surplus value, is appropriated by the property classes (capitalists and landlords) and the state. The wealth accumulated in a society is directly related to the amount of surplus labor time, which is inversely related to the necessary labor time. Furthermore, Marx argued that labor time also regulates the surface phenomena of capitalism, such as the price of commodities. Hence, the law of value—according to which the socially necessary labor time is directly and indirectly embodied in a commodity—is the regulator of the movement of market prices. Prices are the means through which capitalists realize their profits and losses and regulate their behavior accordingly. In Marx, the role of the law of value is analogous to Adam Smith’s “invisible hand,” for it provides an explanation of how capitalist society reproduces itself and the various scales of its reproduction.

There are many different interpretations of Marx, and this often gives the impression that his work is vague. A careful examination of the history of the socialist movement, the origins of which were inspired to a great extent by Marx himself, shows, however, that those engaged in this movement often ignored Marx’s major work, that is, the three volumes of Capital. More specifically, during the period of the First International (1864–1876), Marxists paid particular attention to the political or philosophical writings of Marx and Engels (e.g., the Communist Manifesto (1848), the German Ideology (1845–1846), 1932, etc.). Volume I of Capital (1867) was not read as much as one would expect, except for the “historical” chapters that refer to the exploitation of workers and their struggles for the reduction of the length of the working day. The other chapters were difficult to comprehend, let alone to use in any direct way for the needs of the workers movement. The Marxists of the Second International (1889–1916) began using volume I of Capital and to some extent volume II (published in 1885), which was focused on the mechanisms of reproduction. Their discussions focused on whether Marx’s purpose was to demonstrate the possibility of the balanced growth of capitalism, or to reveal capitalism’s instability and predict its inevitable collapse, unless it expanded to incorporate the noncapitalist economies as an additional source of cheap raw materials and a market to dispose of the products. Hence, the foundation for an economic theory of imperialism was developed by a number of radicals. Volume III of Capital was published in 1894, but was considered “too scientific,” as Rosa Luxemburg (1870–1919) once remarked, and only a few Marxists during the 1930s, notably Henryk Grossmann (1881–1950) and Maurice Dobb (1900–1976), read it attentively. The subsequent Keynesian revolution in economics led many Marxists to “keynesify” the economic theory of Capital and “marxify” the economic policy conclusions of Keynesian economics. The idea is that many Marxists of the time abandoned partly or completely the analysis of Capital and adopted the Keynesian analysis, and from that they tried to derive radical policy conclusions with regard to the treatment of monopolies and income distribution. More specifically, Paul Sweezy (1910–2004) and also Paul Baran (1910–1964) claimed that Marx’s analysis was more appropriate for the conditions of nineteenth-century capitalism, where there were neither monopolies nor a powerful state, than for the current economic situation in which powerful monopolies dominate and together with the state influence economic outcomes. Naturally, many radical economists claimed that once the workers’ party seized power it could use the state for its own purposes. In this context, it has been argued that the law of value no longer holds in conditions of monopoly capitalism and also that Marx’s laws of motion should be revised because the economy is under the control of monopolies and the state. Notable exceptions to this stream of thought were Paul Mattick (1904–1981) and Ernest Mandel (1923–1995), who in the 1970s and 1980s were what Grossmann and Dobb were in the 1920s and 1930s. That is to say, they were from the very few Marxists who consistently used and expanded the analysis of Capital in the conditions of their time.

One might have expected that Marxian economics would flourish during the Soviet era, and it is true that the first decade after the revolution saw the development of theories of medium- and long-term cyclical fluctuations—on the basis of which the technique of material balances was developed. The latter became a tool of national planning and also the starting point for input-output analysis and mathematical economics. Soon, however, Marxism and Marxian economics became dogmatic in the Soviet Union and other East European countries. On the other hand, developments in China, together with student unrest in Europe and the antiwar movement in the United States, sparked a renewed interest in Marxian economics. This time there were systematic efforts to comprehend the totality of Marx’s work and in this context volume III of Capital was integrated into a single eco-
nomic theory that seeks “to lay bare the economic law of motion of modern society” (Marx 1867–1894, Vol. I, p. 10). There were a number of efforts, on the one hand, to clarify and expand Marx’s theoretical scheme and, on the other, to give it empirical content. Thus we find many studies that test the validity of the law of value with input-output data. Similarly, inter-industry data is used to test the law of the tendential equalization of rates of profit across industries, as well as the long-run fall of the general rate of profit and its connection to long-term fluctuations in the level of economic activity. Other topics of interest include extensions of Marx’s work into the areas of international trade, exchange rate determination, the theory of effective demand, the state’s redistributive role, and so on. There is no doubt that in recent decades significant progress has been achieved within Marxian economics, creating a theoretical foundation for further, fertile developments.

Even though the renewed interest in Marxian economics started in non-Soviet countries, the demise of the Soviet Union as well as the dissolution of most Communist parties and the weakening of the labor movement in Western countries during the past few decades have all certainly had a negative effect on the development of Marxian economics. On the positive side, though, one may count the demise of doctrinaire Marxism and the emergence of more pluralistic approaches that have brought to the fore important issues such as gender, race, and the environment. In this sense, the rise to preeminence of China (with its strong Marxist tradition), together with the movement against globalization may give new impetus to the Marxian research program worldwide. This research program has always been under attack and, despite its undeniable progress over recent decades, has never really found much support among Western academic economists. In fact, Marxian economics has always been misunderstood and its importance downplayed by mainstream economics; because of its ideological connotations, it has been relegated, at best, to being a mere chapter in the history of economic thought.

In conclusion, Marx’s most important contribution to political economy was the distinction between labor and labor power, on the basis of which he was able to present a consistent theory of exploitation as a source of profits. Furthermore, he argued that the pursuit of profit as an end in itself has created the laws of motion of capitalist society that operate independently of people’s will. These laws create the objective conditions within which the class struggle and wider political intervention take place. Moreover, Marxian economics integrates macroeconomics (falling rate of profit, reserve army of unemployed) and microeconomics (prices of commodities) through the law of value. Because of this integration, Marxian economics will continue to provide a great deal of fertile ground for further research, at least as long as current orthodox economic theory maintains the dichotomy of micro- and macroeconomics. Only in the last few decades has there been a systematic effort to base macroeconomic analysis and conclusions on solid microeconomic foundations.

ECONOMICS, NEOCLASSICAL

Mainstream economics is often characterized as neoclassical economics, usually to distinguish it from classical economics which had its origin in the rationalist era of the eighteenth century and in particular the work of the patriarch of economics, Adam Smith. The early-twentieth-century critic of economics, Thorstein Veblen, is usually credited with creating the term neoclassical. The obvious reason for the “neo” was that the economics being taught after 1890 somehow went beyond the economics of Smith. While classical economics was concerned with the broad questions facing nations such as growth and development, neoclassical economics instead focused on the decisions of independent and autonomous individuals who participate in the economy.

There are two fundamental ideas that characterize neoclassical economics: A metaphysical one about what motivates individuals to choose one option rather than another and a methodological one about the essential elements of any neoclassical explanation.

THE METAPHYSICS OF NEOCLASSICAL ECONOMICS

The primary and only behavioral assumption of neoclassical economics is that an individual is motivated to do what is best for him or her. To keep in touch with its eighteenth-century roots, this is commonly stated as: People are rational. While many economists mistakenly see this as
a proposition about psychology, in reality it has nothing to do with psychology. A choice (or decision) is rational only if one can state a rational argument that entails the choice at issue. As such, rationality is always an attribute of the argument, not the mind.

Usually, an argument consists of several statements identifying explicit assumptions or reasons that are asserted to be true. These are connected by means of ordinary logic to form a logical structure defined by logical connective words (and, or, if) and words formed from the verb “to be.” Usual arguments include quantitative relational words (some, all, and at least one). To be a rational argument, two conditions must be met. Everyone who accepts the truth of all of the assumptions of a logically valid argument must accept the truth of all statements entailed (or predicted) by the argument. The first essential condition involves the term anyone. That is, rationality is universal and it is its universality that makes it useful as an explanation of a choice made by an individual. The second essential condition is that each statement entailed by the argument is unique. When the entailed statement represents the one choice an individual makes as in the case of every neoclassical explanation, that choice must be unique. That is, anyone who accepts the truth status of all of the assumptions of the economic theorist’s explanation will reach exactly the same conclusion concerning the individual’s choice made.

While these conditions of universality and uniqueness likely were taken for granted in the eighteenth-century conception of rationality, neoclassical economics of the late nineteenth century chose to express rationality as maximization (which historians of economic thought call marginalism). The idea of a maximizing choice captures the necessary ingredients of any rational argument. For example, it says that whenever choosing how much to consume of some good, individuals are motivated to maximize their level of satisfaction subject to three things: the limitations of the budget, the going price of the good, and the personal "utility function" (which is the mathematical relation that indicates the quantitative level of satisfaction obtained when consuming each possible total amount of that good). While everyone faces the same price, each individual has a personally specific utility function as well as a specific budget. Thus, a maximizing individual will be said to choose that singular quantity of the good that yields the maximum level of satisfaction. Moreover, the explanation also implies that any individual who has specifically the same utility function, facing the same budget and price will make exactly the same choice. As such then, the maximization explanation fulfills the conditions of a rational explanation as it is both universal and unique. And one can always construct an analogous explanation of the choices made by the producers of the product where their motivation may be assumed to be profit maximization.

THE METHODOLOGY OF INDIVIDUALISM

In neoclassical economics things do not decide, only individuals do. This is called methodological individualism. It means that in neoclassical economics any social event must be explained as being the unintended aggregative consequence of the maximizing decisions and choices made by the independent and autonomous individuals participating in the economy or society. Of course, individuals are constrained by existing institutions and laws but this does not invalidate the neoclassical conception of individualism. Instead, it just says that whatever constrains individuals other than nature-given constraints such as weather and resource endowments must be explained. All institutions and laws are the consequence of decisions made by other individuals and thus can and must be explained in any complete neoclassical explanation.

It is the explicit mathematical analysis of the individual decision maker that primarily distinguishes neoclassical from classical economics and the latter’s focus on the nation as a whole. But in principle the end result cannot be different, only the emphasis is different. Whatever the nation is, it is the result of decisions made by all of its constituents both past and present. So, when one explains how each and every individual makes or made their choices, one has explained the whole economy.

The two writers credited with promoting this individualist economics were the Cambridge economist Alfred Marshall and the French economist Léon Walras. Marshall focused on the method of partial equilibrium analysis which recognizes that individuals must take things like prices and product availability as given and do the best they can with the few things they can decide or choose; Walras was instead concerned with general equilibrium analysis for the whole economy and in particular the logical requirements for the determination of a system of prices that would allow all individuals to be maximizing simultaneously. Specifying the necessary mathematical requirements for such a general equilibrium is not trivial and remains a puzzle even in the twenty-first century. While it is always possible to specify assumptions that are sufficient to produce such equilibria, it is another thing to specify assumptions that are necessary.

It is important to note that going beyond the narrow confines of equilibrium analysis, the maximizing individual is still a useful concept even when explaining change or disequilibrium. Specifically, individuals are motivated to change whenever they think they are not maximizing. If the amount of a good an individual would want to buy is not available, that individual could offer to pay a higher price.
Thus change, too, is compatible with methodological individualism. So, with this in mind, even a changing world could be seen to be amenable to neoclassical analysis.

THE POSSIBLE LIMITATIONS OF NEOCLASSICAL ECONOMICS

It is easy to see why anyone would think neoclassical economics could be used to explain every social fact or event. Examples are marriage decisions, career decisions, voting patterns, and so on. A generalized form of neoclassical economics can be found in other social sciences under the name of rational choice theory. The philosopher Karl Popper called it “situational analysis.” But critics of neoclassical economics still find it reasonable to doubt the usefulness of such explanations. The primary criticism is based on asking the troublesome question: What must a rational decision maker know in order to make a successful maximizing choice? As Friedrich Hayek in 1937 argued, at minimum, the theorist must identify how the decision makers come to know their choice is the maximizing one. For the most part neoclassical economists have been slow in taking-up Hayek’s suggestion. Instead, neoclassical economists have continued by knowingly making conceivably false assumptions about the economy, usually assuming that all participants in the economy are successfully maximizing with all decisions and choices, and on that basis construct social policies concerning tax rates, interest rates, trade policies, and the like. And critics of such policies continue claiming it is unrealistic to assume everyone is capable of such successful behavior.

Such criticism is not new, however. In the early 1940s, critics such as Richard Lester claimed that empirical evidence did not support the assumption that decision makers in manufacturing firms consciously did the intricate calculations needed to maximize profit as required by the calculus of maximization. In response to such criticism, Armen Alchian in a social-Darwinian fashion argued in 1950 that conscious maximization (and hence deliberate calculation) is unnecessary for success. His argument was based on the notion that if the economy is in a long-run equilibrium—that is, not only are all markets cleared but there has been sufficient time for every producer to have made the optimum decision concerning which markets to enter—then every firm is making what neoclassical economists call zero excess profit. Zero excess profit merely means that the price charged for the product just covers all costs including the normal rate of return expected by owners and investors. In such a world, Alchian notes, the only survivors are those firms maximizing profit—whether or not they deliberately set about applying calculus. That is, in a state of long-run equilibrium, the maximum (excess) profit is zero and thus any firm not maximizing cannot cover all costs and hence cannot survive.

The question of the acceptability of knowingly employing false assumptions when forming economic policy has been a continuing object of dispute since 1953 when Milton Friedman made his argument in favor of an instrumentalist methodology in his famous essay. His argument simply said that as long as the theory works when put to practical use as a tool, the truth status of the constituent assumptions does not matter. Since 1953 economists can be divided into two groups: those that agree with Friedman’s essay and those that do not. While most methodologists are critical of Friedman’s essay or instrumentalism in general, economists who are engaged in practical policy issues are often willing to accept false assumptions as approximations and thus push on with their practical efforts. And as long as the practical uses of such assumptions are seen to yield successful policies, methodologists who demand realism will likely find an audience only among the many critics of neoclassical economics who object to its emphasis of individual maximization as the sole motivation for decision making.

ECONOMICS, NEO-RICARDIAN

Neo-Ricardian economics is a school of thought that aims to revive classical economics, which flourished during the
eighteenth and nineteenth centuries, by reformulating it analytically and extending its approach to economic theorizing. As discussed below, neo-Ricardians focus on the classical theory of value and distribution originally elaborated by Adam Smith and subsequently amended, reformulated, and systematized by David Ricardo.

The earliest use of the term neo-Ricardian can be traced to the eminent neoclassical economist Dennis Holme Robertson. Bob Rowthorn (1974) was the first to identify a school with this term. The contributions of Piero Sraffa—in particular, the editing of and the introduction to Volume I of The Collected Works and Correspondence of David Ricardo (1951) and the short but dense book Production of Commodities by Means of Commodities (1960)—played a crucial role in the development of the neo-Ricardian or (after him) Sraffian approach. Sraffa's objectives, as revealed in a small number of published works and an enormous archive of unpublished manuscripts, were: (1) to revive and clarify the tradition of the classical economists from Adam Smith to David Ricardo, including Karl Marx; (2) to expose the weaknesses besetting the neoclassical theory of value and distribution; (3) to construct a coherent approach to economic theorizing that maintains the classical methodology and perspective.

Neo-Ricardian economics had a prominent position in the literature in the 1960s and early 1970s, during the “Cambridge capital controversy” between neoclassical economists centered mainly at MIT (the “Cambridge” of America) and neo-Ricardian economists at Cambridge University in England (for a detailed account see Harcourt 1972). The central theme of the debates was the questioning of the very notion of aggregate capital as a physical, measurable quantity and of the validity of the neoclassical theory of distribution based on such a concept. Even though the neo-Ricardian critique was correct, following the early 1970s the interest of the profession drifted away from the ‘paradoxes’ of capital theory. By the 1980s, there was little attention to the difficulties inherent in the aggregation of capital in the formulation of economic models. As suggested by Luigi Pasinetti (2000), the suppression of the contradictions in the neoclassical theory of capital is evidence of the Kuhnian mechanism by which a dominant paradigm is defended against apparent anomalies.

In the following years, neo-Ricardian scholars applied increasing effort to building up their approach. A short list of journals that publish their contributions includes The Cambridge Journal of Economics, The Review of Political Economy, Metroeconomica, and Contributions to Political Economy. Today, neo-Ricardian economics is well grounded, yet still much in need of theoretical development.

The core of the neo-Ricardian approach to value and distribution is the determination of the size of the social surplus (Garegnani 1984), that is, what is left of the social product after subtracting the inputs necessary to restart the production cycle (the used-up means of production and subsistence wages). Analysis involves the following independent variables:

1. the set of techniques available to producers;
2. the size and composition of the social product;
3. one of the distributive variables—either the wage rate or the rate of profit;
4. the existing stock of natural resources.

These givens are sufficient to identify the “normal” or “long-period” position of an economy, which corresponds to a set of values for the relevant variables: relative prices (derived by using the cost-minimizing technique, which minimizes the cost of production), the social surplus, and—excluding, for simplicity, land rentals—the other distributive variable, the rate of profit or the wage rate. Under conditions of free competition, the long-period position is characterized by the equalization of the profit rate throughout the economy. The economy does not necessarily settle into a long-run position, due to changing economic circumstances that cause shifts. However, there is a presumption that “current” or “market” values continuously gravitate toward the corresponding natural or normal values. The underlying dynamic process is based on the idea that capital-owners move capital between sectors in search of the highest remuneration (for a review of modern analytical formulations of the gravitational process, see Kubin 1991).

The important features of the above analysis are: (1) deductive reasoning; (2) objectivism, that is, the use of data that are directly observable, measurable, or calculable; and (3) the asymmetric treatment of the distributive variables—that is, the treatment of one as an independent variable.

DIFFERENCES BETWEEN NEO-RICARDIAN AND NEOCLASSICAL APPROACHES

The objectivism of neo-Ricardian economics contrasts with neoclassical subjectivism, which allows for variables that are not directly observable within the initial set of data. The neoclassical data set consists of: (1) the set of techniques available to producers; (2) the preferences of consumers; and (3) the initial endowments of individual agents, including all the means of production, both produced (i.e., capital) and non-produced (i.e., land and labor). In neoclassical theory, all factors of production are treated symmetrically in terms of their scarcity. For each
of them there are analogous demand and supply functions for their productive services. Equilibrium quantities and prices correspond to the intersection of these functions. This approach requires quantities of labor and capital that are unambiguously measurable and independent of their remunerations.

However, as the Cambridge controversies highlighted, capital cannot be treated in the same way as the other factors of production. In fact, though we may envisage a long-run equilibrium (the neoclassical equivalent of a long-period position) involving different types of labor with different remunerations, an equilibrium with heterogeneous capital goods and many rates of profit cannot exist. The existence of a tendency toward a uniform rate of profit, enforced by free competition, makes the determination of a unique equilibrium impossible if capital is treated in kind. Only after capital is expressed in “value” terms is it possible to construct a coherent aggregate production function (the basic tool of neoclassical macroeconomic analyses) in which all factors of production play the same role and from which demand functions for factor services can be derived through differentiation.

However, a measure of capital in value terms is affected by changes in the rate of profit (and in relative prices) giving rise to the possible occurrence of the phenomena known as reverse capital deepening and reswitching of techniques. The latter can be described taking the simplest case of only two techniques of production $\alpha$ and $\beta$ with different capital intensities. Suppose that $\alpha$, which is more profitable at lower rates of profit, is the technique in use. As the profit rate increases, producers may find $\beta$ more profitable and switch from $\alpha$ to $\beta$. However, as the profit rate increases further, $\alpha$ could become the more profitable technique, so producers are induced to switch back to it. Reswitching is a sufficient but not necessary condition for capital reversing (Garegnani 1970). The latter phenomenon is a change in direction (from negative to positive) of the relationship between the capital/labor ratio (or the capital/output ratio) and the profit rate.

The occurrence of capital reversing (and a fortiori of reswitching of techniques), which excludes smooth production functions (both at the industry and the economy levels), does not rule out the possibility of constructing more “irregular” but logically coherent technological relationships between capital and the rate of profit (for an application, see Kurz and Salvadori 1995).

NEW LINES OF RESEARCH FOR NEO-RICARDIANISM

A clear weakness of neo-Ricardian economics is the lack of a comprehensive perspective on all the relevant aspects of economic enquiry; much remains to be investigated outside the core theory of value and distribution. Indeed, some suggest that as yet no well-defined neo-Ricardian school can be identified (see Roncaglia 1991). Tony Aspromourgos (2004) provides a detailed review of current neo-Ricardian developments and research projects, some of which include:

1. The identification of a “Classical” theory of endogenous growth in which different types of technology are taken into account (Kurz and Salvadori 1998)

2. The Sraffa-Keynes synthesis, whereby the social product (or, in its long-period version, its growth rate) is determined by the autonomous components of demand (or their growth rates). This synthesis requires some form of harmonization between effective demand and the notions of normal prices (corresponding to the uniform rate of profit) and normal productive-capacity utilization (Garegnani 1978, 1979, and 1992)

3. An explanation of changes in the composition of demand with a Classical flavor, but employing modern analytical tools (Schefold 1985)

4. A monetary theory of distribution—elaborated by Panico (1988) and Pivetti (1991) following Sraffa’s suggestion (Production of Commodities, p. 33)—according to which the rate of profit can be determined by the monetary rate of interest, fixed exogenously by the monetary authority

5. The incorporation of renewable and exhaustible resources (Bidard 2004)

Economics, New Classical

ECONOMICS, NEW CLASSICAL

New classical economics takes the view that short-run fluctuations in the aggregate economy—the business cycle—can be understood within an equilibrium framework of rational, forward-looking agents, without relying on the presumption that market rigidities or imperfections (such as sticky prices), and the consequent disequilibrium adjustment as articulated in John Maynard Keynes’s (1883–1946) General Theory of Employment, Interest, and Money (1936), are necessary to explain the cyclical behavior of the macroeconomy. New classical economics assumes universal market clearing, rational expectations, an equilibrium or “natural” rate of employment and output, and labor suppliers who respond rationally to intertemporal relative prices. At the same time, it assumes that information about relative prices is costly to obtain and therefore imperfect, which can provide a means for aggregate demand to act as a determinant of real economic activity.

This school of thought is known as the new classical economics because it builds on the general equilibrium principles of classical economics to give aggregate demand a causal role in explaining observed correlations among prices, income, employment, and money. Such a role is difficult to find in the writings of the pre-Keynesian classical economists, who tended to view the overall market economy as self-adjusting and aggregate demand as being neutral in its effects on the economy.

New classical economics has its genesis in the work of Nobel laureate Robert E. Lucas Jr. Lucas summarizes the new classical approach and justifies its insistence on explaining business cycles using equilibrium models of economic behavior, that is, models that “account for the observed movements in quantities … as an optimizing response to observed movements in prices” (1977, p. 14). Elsewhere, Lucas (1980) discusses the new classical view in the historical context of business cycle theory.

Lucas and Leonard Rapping (1969) made the first attempt to explain aggregate employment and wage behavior based on a dynamic theory of competitive labor market equilibrium. The Lucas-Rapping model relies on a precise formulation of households’ optimal choices of labor and leisure over time. This approach has since become the foundation for dynamic macroeconomic models.

Because the Lucas-Rapping model rules out disequilibrium adjustment in the labor market, it must account for short-run fluctuations in employment owing to real wage changes, while remaining consistent with the accepted fact that employment is independent of real wages in the long-run. It does so through appeal to the intertemporal substitution of labor and leisure—the response of workers to incentives to alter their supply of labor across different periods of time. Suppose that labor suppliers face wages temporarily below their expected normal or long-run levels. Dynamic utility maximization implies that these workers will respond by reducing hours

Pasquale Commendatore
of work today (that is, by increasing the consumption of leisure today), and increasing work in the future, at the expense of future leisure. The response of rational, forward-looking agents to changes in intertemporal relative prices is a cornerstone of new classical economics, and indeed of modern macroeconomics.

Drawing further inspiration from Edmund Phelps et al. (1970), Lucas (1972, 1973) goes on to develop a general equilibrium extension to the Lucas-Rapping partial equilibrium model of the labor market. His primary motivation is to explain the positive empirical correlation of money and output while retaining the “classical” assumptions that consumers and producers respond rationally to relative prices, that all markets clear, and that expectations are rational—agents’ forecasts of unknown variables relevant for decisions are, on average, unbiased conditional on available information. Taken alone, the classical assumptions suggest a world in which money and nominal aggregate demand are neutral, affecting all nominal prices proportionately and therefore leaving relative prices and real activity unaltered. The challenge Lucas faced is therefore one of accounting for monetary nonneutralities while avoiding appeal to nonclassical (Keynesian) frictions.

Lucas meets this challenge by assuming, as suggested by Phelps, that information does not flow freely across markets, so that rational (Lucas-Rapping) producers mistake common money supply shocks with market-specific supply and demand shocks. Ideally, producers base supply decisions on their going market price relative to prices in all other markets (as summarized by the price level). However, a lack of current information concerning other prices prevents local producers from knowing with certainty what the overall price level is. An unperceived economy-wide increase in the money stock, which tends to raise demand and prices in all markets, will therefore be perceived by the individual producer as an increase in his or her product’s relative price. The producer’s rational response in this case is to increase production. Because all producers are similarly confused, the nominal money shock will increase overall output, which would not be the case if information flowed freely.

Lucas’s “imperfect-information” model further implies that the extent of producers’ confusion regarding the sources of movements in market prices depends on the volatility of economy-wide shocks relative to market-specific shocks. In particular, in economies with high aggregate demand variance, producers are reasonably sure that a change in their market price is caused by an aggregate shock (thus leading the price level, not relative prices, to change) since these shocks are typically large relative to market-specific shocks. In this case, producers will have little incentive to respond to any given aggregate shock by altering production, because they are less likely to be “fooled.” Lucas (1973) explicitly tests this implication using cross-country data and finds that countries with relatively high aggregate demand variability respond less to aggregate demand shocks than countries with relatively low aggregate demand variability, a finding consistent with his theory.

The so-called Lucas supply curve, which makes explicit the dependence of output on the difference between the realized and expected price level, is the new classical reformulation of the expectations-augmented Phillips curve of Milton Friedman (1968) and Phelps (1968). The new classical approach is consistent with the natural rate hypothesis of Friedman and Phelps—that deviations in output from its natural or full-employment level cannot be sustained without a sustained deviation of actual from expected inflation.

The rational expectations hypothesis, conceived by John Muth (1961) and formalized by Lucas and Edward Prescott (1971), is an essential (though not unique) feature of new classical economics and an important innovation in the study of macroeconomics. It applies the basic principles of rational, economic behavior to forecasting, requiring economic agents to equate their “subjective” probabilities with those “objective” probabilities implied by the model itself. Lucas justifies rational expectations based on the implausibility of systematic forecast errors in the face of the “recurrent character of the [business] cycle” (1977, p. 15). Indeed, rational expectations are now assumed in most macroeconomic models, including ones that do not take market-clearing prices for granted and therefore fall outside the boundaries of new classical economics.

Lucas’s work and the new classical economics it has fostered have had a lasting influence on our understanding of the effects of aggregate demand policies, in particular monetary policy, on the economy. One of the most important implications, further developed by Thomas Sargent and Neil Wallace (1975), is the policy ineffectiveness proposition. Lucas’s canonical new classical model implies that only unanticipated shocks to money or aggregate demand can alter incentives; anticipated shocks will be quickly incorporated into all nominal magnitudes, so that relative prices will remain unaltered. Therefore, systematic monetary policies—those manipulations of money and interest rates by the central bank that are anticipated by market participants—can have no hope of influencing income or employment. This implication provides theoretical backbone to Friedman’s earlier proposal for a constant money growth rule, while condemning the “fine-tuning” policies of the 1960s and 1970s.

A corollary to the ineffectiveness proposition is that credible changes in policy rules can have immediate effects on inflation without much effect on output. Sargent
(1982) shows convincingly that some historical episodes of "big inflations" ended quickly without severe recessions when people fully understood and anticipated permanent anti-inflation reforms. 

The consensus view of macroeconomists today is that the imperfect-information theory of new classical economics is not satisfactorily borne out by the data, and is therefore inadequate for understanding business cycles or providing a framework for policy analysis (see, for example, Woodford 2003, p. 6). Nonetheless, its influence continues beyond the now common use of the assumption of rational expectations. Real business cycle theories, first formulated by Finn Kydland and Prescott (1982), take up the mantle of equilibrium economics from the new classical paradigm, but emphasize the role of "real" shocks—shocks to preferences and technology—as the sources of aggregate fluctuations as opposed to nominal or monetary shocks. On the other hand, and somewhat ironically, the new classical critique of Keynesian models that they lack theoretical foundations for market and price rigidities has led to a resurgence of such models. The reaction to this critique, new Keynesian economics, attempts to explain such rigidities as the outcome of optimizing behavior on the part of rational agents. The papers in N. Gregory Mankiw and David Romer (1991) provide a good summary of some of the early work in this vein.

ECONOMICS, NEW KEYNESIAN

The macroeconomic debates on the effectiveness of fiscal and monetary policy have raged for many decades on both sides of the Atlantic. Up to the 1970s many economists and policymakers believed in a short-run Keynesian trade-off between inflation and unemployment (termed a Phillips Curve), so that an expansionary fiscal or monetary policy would at least boost employment and lower unemployment for some time. The accelerator hypothesis popular in the 1970s insisted that extra jobs could only be achieved at the expense of ever-increasing inflation. The critique of econometric policy evaluation put forward by Robert Lucas in 1976 insisted that people cannot be fooled all the time. The subsequent outburst of new classical economics led by Lucas and Thomas Sargent and Neil Wallace killed the popularity of Keynesian economics.

By the end of the 1970s policymakers and economists became skeptical about the possibility of expansionary demand management lowering unemployment. The new classical economists rejected Keynesian theories of aggregate demand with sluggish price and wage formation and insisted on modelling dynamic, competitive general equilibrium models with rigorous micro foundations, rational expectations, and prices and wages adjusting instantaneously to clear all goods and labor markets. Fluctuations thus arise from technology shocks rather than changes in economic policy. This generation of economists works in the spirit of classical economists like Adam Smith, David Hume, David Ricardo, John Stuart Mill, Knut Wicksell,
Irving Fisher, and John Maynard Keynes of The Treatise of Money (1930) who all insisted that output is primarily determined by productive capacity.

However, in 1980 Robert Solow (1980) in his Presidential Address to the American Economic Association criticized the new classical school and its Panglossian policy prescriptions for being unrealistic and irrelevant. He missed returns to scale and oligopolistic interdependence, and was unable to accept that all unemployed households are voluntarily unemployed. Involuntary unemployment and non-clearing labor markets needed to be addressed, which, according to Solow, would require an analysis of real and nominal wage and price rigidities, which may well follow from optimizing behavior of agents in the economy during their normal activities. Solow gave a host of reasons why labor markets do not clear immediately (varying from Keynes’s idea of case-by-case resistance to wage reductions to trade unions and efficiency wages).

Soon afterward, Oliver Hart, Oliver Blanchard, and Nobu Kiyotaki, and others in Gregory Mankiw and David Romer’s New Keynesian Economics (1991) explained that aggregate demand externalities in economies with monopolistic competition produces Keynesian multipliers. With small menu costs prices can be rigid and monetary policy has real effects on the economy. In the 2000s Michael Woodford (2003) and Jordi Gali (2003) continued the New Keynesian counter-attack on the new classical orthodoxy. Their objective is to develop dynamic, noncompetitive general equilibrium models with rigorous microfoundations, but where it is costly to adjust prices instantaneously. They obtain a micro-founded, forward-looking New Keynesian Phillips Curve with a short-run trade-off between inflation and unemployment. The main advantage of this approach is that a second-order approximation to a proper micro-founded welfare loss function can be obtained. This leads to the advice that central bankers should not target the actual output gap, but should target the economy as close as possible to the level of output that would prevail under flexible wages and prices.

An important implication is that inflation is forward rather than backward looking. The reason is that prices stay fixed for a while and thus depend on expected future marginal costs and demand conditions. A big difference with the accelerator version of the Phillips Curve is that inflation leads output rather than the other way round. A monetary expansion always expands output, but only generates a lower interest rate if risk aversion is sufficiently high and money growth is not too autocorrelated. The Keynesian liquidity effect is thus not necessarily operative in the New Neoclassical Synthesis. Another insight is that policymakers should target deviations of actual output from the first-best level of output that would prevail in the absence of price and wage rigidity rather than from the de-trended level of output.

The New Keynesian approach cannot explain the quintessential Keynesian features that inflation displays inertia and monetary disinflations are contractionary. Other challenges for the New Keynesian approach are to explain pro-cyclical real wages in the face of demand shocks, allow for inventories, credit constraints, and bankruptcies in explaining the business cycle, model unemployment as a catastrophic event, and allow for psychological features such as downward rigidity of wages and not taking account of the full effects of changes in inflation at low rates of inflation.

Keynesian economics was not popular in the 1970s and 1980s. However, with the advent of New Keynesian economics, Keynes has become a source of inspiration again. Apart from giving more rigorous microfoundations, an important factor is undoubtedly that Keynesian economics is better able to explain the events of the 1970s and the 1980s as well as the recessions of the late twentieth century than the new classical economics. The New Keynesian approach must be able to explain periods of persistent, widespread involuntary unemployment, since otherwise it does not capture quintessential Keynesian features. One cannot rely on people’s misperceptions about relative prices or technology shocks alone to explain such periods. Keynes stressed the importance of animal spirits, coordination failures, and the possibility of multiple equilibrium outcomes. Coordination failures and bootstrap equilibria are important, since economies can get stuck in situations of deficient demand and widespread unemployment. Policymakers must then react by boosting confidence in the economy again. Investment by firms is financed by retained profits rather than borrowing, and this together with changes in the functional distribution of income is an important source of macroeconomic fluctuations. However, neither traditional nor New Keynesian Phillips Curves capture real world features that affect firm and bank behavior such as credit constraints, equity constraints, bankruptcies, and other market failures arising from imperfect information as discussed in Joseph Stiglitz and Bruce Greenwald’s Towards a New Paradigm in Monetary Economics (2003). If allowance is made for these features and the role of financial intermediaries, it follows that the nominal interest rate as well as the real interest rate affects the aggregate demand for goods. Monetary policy is associated with big distortions in allocation and is as much about supervision and regulation as the interest rate.

ECONOMICS, NOBEL 
PRIZE IN
The Bank of Sweden Prize in Economic Sciences in Memory of Alfred Nobel, the founder of the Nobel Prize, 
was instituted by the Bank of Sweden (the world’s oldest 
central bank) for its three-hundredth anniversary in 1968, 
sixty-seven years after the first Nobel Prizes were awarded 
for other fields. Known also as the Nobel Memorial Prize in 
Economics, and less formally as the Nobel Prize in 
Economics, it is the only prize granted that was not specified in 
Alfred Nobel’s will. Its addition was justified as a 
recognition that the use of quantitative methods had 
made economics a science like physics and chemistry.

The Nobel Prize in Economics is awarded each year 
for outstanding intellectual contributions to the field of 
economics. The laureates are chosen by the Royal Swedish 
Academy of Sciences, from nominations of about one 
hundred living persons made by qualified nominators 
each year. Prizewinners receive their award during a cerem-
ony in Stockholm, together with the laureates in the other 
fields. No more than three people can share the 
prize for a given year. The names of the nominees can only 
be published after fifty years.

From 1969, when the first prize was awarded, up to 
2006, fifty-eight people have received the Nobel in eco-
nomics. Economics is the only discipline in which no 
woman has ever been awarded a Nobel. The United States 
has dominated the award, with forty laureates, followed 
by nine laureates from the United Kingdom. The 
University of Chicago has employed the highest number of 
lauares in economics, nine up to 2006, followed by 
Harvard University and U.C. Berkeley, with four laureates 
each. Out of the thirty-eight prizes awarded up to 2006, 
seventeen were shared. With an average age of sixty-six at the 
time of the award, laureates in economics are the oldest to receive the prize—the youngest are in physics, with an 
average age of fifty-four. The youngest person to receive the prize in economics was Kenneth Arrow, in 1972, at the age of fifty-one; the oldest was Thomas 
Schelling, in 2005, at the age of eighty-four.

The prize has been awarded to work ranging from 
thory to empirical application, from macroeconomics to 
microeconomics, from economic policy to economic history, and from mathematical modeling to psychology. The early awards were focused on acknowledging the past contributions of “giants” such as Paul Samuelson (1970), 
the father of the modern economic theory; Simon Kuznets 
(1971), the father of the empirical analysis of economic growth; John Hicks and Kenneth Arrow (1972), pioneering 
contributors to general economic equilibrium theory and welfare theory; Wassily Leontief (1973), who developed the input-output method and a number of applications to economic problems; and Milton Friedman 
(1976), whose long list of contributions include consumption analysis, monetary history and theory, and sta-
bilization policy.

The scope of the award has been broadened over the 
decades, while the work awarded has become more 
specialized. One could already see these trends in the 
1980s, with prizes given for work on the theory of eco-
nomic growth (Robert Solow, 1987), financial economics 
(James Tobin, 1981; Franco Modigliani, 1985; Harry 
Markowitz, Merton Miller, and William Sharpe, 1990), 
empirical work and econometrics (Lawrence Klein, 1980; 
Richard Stone, 1984; Trygve Haavelmo, 1989), and eco-
These trends have become even more apparent in recent years. Since 1990, the prize has been awarded for contributions that address economic problems with tools and results from fields outside economics, such as mathematics and game theory (John Harsanyi, John Nash and Reinhard Selten, 1994; Robert J. Aumann and Thomas Schelling, 2005), psychology (Daniel Kahneman and Vernon Smith, 2002), and philosophy (Amartya Sen, 1998). It has also been given for contributions that apply economic tools to other fields, such as work that uses microeconomic analysis to explain a wide range of human behavior and interaction (Gary Becker, 1992), and work using economic theory and quantitative methods to explain economic and institutional change in history (Robert Fogel and Douglass North, 1993). It has been awarded for econometrics (James Heckman and Daniel McFadden, 2000; Robert Engle and Clive Granger, 2003), and for broadening and deepening economic theory by incorporating transaction costs and property rights (Ronald Coase, 1991), rational expectations (Robert Lucas, 1995), and asymmetric information (George Akerlof, Michael Spence, and Joseph Stiglitz, 2001). It has also been given for work with direct policy implications, such as that addressing monetary and fiscal policy under different exchange rate regimes (Robert Mundell, 1999) and the intertemporal trade-offs in macroeconomic policy (Phelps 2006), and for contributions that were first criticized as too specialized and limited in scope, but later proved more influential and applicable than most had expected, such as the pricing formula for financial derivatives (Robert Merton and Myron Scholes, 1997).

The Nobel Prize in Economics has been a source of controversy since its introduction. Some have even suggested that the award should be discontinued. Its very name has been questioned, as it was not part of Alfred Nobel's bequest. It has also been argued that the criteria for an award for a social science cannot be as objective as for the other fields, although similar concerns have been raised for the prizes for peace and literature. Indeed, this may explain why it takes much longer to receive the Nobel in Economics after a contribution is made than in any other field—an average of thirty-three years, compared with an average of twelve years for prizes in the hard sciences—which has also been a source of controversy. Finally, some of the recent selections have been criticized for honoring contributions that are too narrowly focused.

The prize has affected both the field of economics itself and the field's impact. It has been argued that the prospect of receiving a Nobel Prize motivates economists to pursue original research ideas. Although there has been no empirical study documenting such an effect, it is consistent with one of the most basic laws in economics that people respond to incentives. The impact that an economist has is substantially enhanced if they can add the title Nobel Laureate after their name. Elite universities lose no opportunity to advertise the laureates on their faculty to attract new faculty members and graduate students. Even Hollywood has been inspired by the prestige of the prize, as reflected in the Oscar-winning movie A Beautiful Mind, about the life of John Nash.

ECONOMICS, POST KEYNESIAN

John Maynard Keynes's 1936 book The General Theory of Employment, Interest, and Money attempted to overthrow classical theory and revolutionize how economists think about the economy. Economists who build upon Keynes's General Theory to analyze the economic problems of the twenty-first-century global economy are called Post Keynesians. Keynes's "principle of effective demand" (1936, chap. 2) declared that the axioms underlying classical theory were not applicable to a money-using, entrepreneurial economic system. Consequently, the mainstream theory's "teaching is misleading and disastrous if we attempt to apply it to the facts of experience" (Keynes 1936, p. 3). To develop an economic theory applicable to a monetary economy, Keynes suggested rejecting three basic axioms of classical economics (1936, p. 16).

Unfortunately, the axioms that Keynes suggested for rejection are still part of the foundation of twenty-first-century mainstream economic theory. Post Keynesians have thrown out the three axioms that Keynes suggested rejecting in The General Theory. The rejected axioms are the ergodic axiom, the gross-substitution axiom, and the neutral-money axiom, which are explained below. Only if these axioms are rejected can a model be developed that has the following characteristics:

• Money matters in the long and short run, that is, changes in the money supply can affect decisions that determine the level of employment and real economic output.

• As the economic system moves from an irrevocable past to an uncertain future, decision makers recognize that they make important, costly decisions in uncertain conditions where reliable, rational calculations regarding the future are impossible.

• People and organizations enter into monetary contracts. These money contracts are a human institution developed to efficiently organize time-consuming production and exchange processes. The money-wage contract is the most ubiquitous of these contracts.

• Unemployment, rather than full employment, is a common laissez-faire situation in a market-oriented, monetary production economy.

The ergodic axiom postulates that all future events are actuarially certain, that is, that the future can be accurately forecasted from an analysis of existing market data. Consequently, this axiom implies that income earned at any employment level is entirely spent either on produced goods for today's consumption or on buying investment goods that will be used to produce goods for the (known) future consumption of today's savers. In other words, orthodox theory assumes that all income is always immediately spent on producibles, so there is never a lack of effective demand for things that industry can produce at full employment. The proportion of income that households save does not affect total (aggregate) demand for producibles; it affects only the composition of demand (and production) between consumption and investment goods. Thus, saving creates jobs in the capital-goods-producing industries just as much as consumption spending creates jobs in the consumer-goods-producing industries. Post Keynesian theory rejects the ergodic axiom.

In Post Keynesian theory, however, people recognize that the future is uncertain (nonergodic) and cannot be reliably predicted. Consequently, people decide on how
much of current income is spent on consumer goods and how much is not spent on consumption goods but is instead saved by purchasing various liquid assets.

Liquid assets are time-machine vehicles that savers use to store and transport savings to an indefinite future date or dates. Unlike savers in the classical system who can reliably predict their economic future, real-world savers do not know exactly what they will buy, and what contractual obligations they will incur, at any specific future date. As long as money discharges all contractual obligations and monetary contracts are used to organize production and exchange activities, the possession of money (and liquid assets that have small carrying costs and can be easily resold for money) means that holding one savings in the form of liquid assets gives savers the ability to demand products whenever they desire in the uncertain future and/or to meet a future unforeseen contractual commitment. Liquid assets are savers’ security blankets, protecting them from possible hard times. As Nobel Price winner John Hicks has stated, income recipients know that they “do not know just what will happen in the future” (1977, p. vii).

Keynes (1936, chap. 17) argued that money (and all liquid assets) have two essential properties. First, money does not grow on trees, and hence labor cannot be hired to harvest money trees when income earners reduce consumption to save more in the form of money or liquid assets. Accordingly, the decision to consume rather than to save is a choice between an employment-inducing demand and a non-employment-inducing demand. When savings increase at the expense of the demand for producibles, sales and employment decline. Second, liquid asset prices will increase as new savings increase the demand for such assets. Because of high carrying and high resale costs, producible durables are not gross substitutes for liquid assets, contrary to the classical gross-substitution axiom where the latter assumes anything is a good substitute for anything else. Post Keynesians reject the gross substitution axiom as applicable to assets that savers use to store their savings. Consequently, higher liquid-asset prices do not divert this savings demand for liquid assets to a demand for producibles with whose relative price has declined. (If producibles were gross substitutes for liquid assets and if savings increase the relative price of liquid nonproducible assets, then the gross substitution axiom implies that savers would be induced to substitute the lower relative priced producibles as a place for their savings. Thus savings would create a simultaneous demand for the durable producibles and there would never be a lack of effective demand for the products of industry.)

In the real world, investment spending on producible durables is constrained solely by entrepreneurs’ expectations of profits. If the future is uncertain, these expecta-

**ECONOMICS, PUBLIC**

Public economics is often defined as the economic study of the public sector. Contemporary public economics draws from two traditions, public finance and public choice. The older public finance tradition of economists such as Arthur Pigou and Richard Musgrave views government as essentially benevolent. The roles of government are, first, to raise funds and provide basic public goods, such as national defense; second, to correct market failure, namely the failure of markets to achieve efficiency in the presence of externalities, public goods, and imperfect information; and third, to improve equity. Equity is viewed primarily in terms of income distribution, and so more equity is generally associated with less inequality in the distribution of income.

Unlike many other areas of mainstream economics, much of the public finance literature is explicitly normative. For example, optimal tax theory prescribes how governments should raise revenue so as to achieve both equity and efficiency. The American Economic Association's
Journal of Economic Literature classification system reflects the public finance tradition, categorizing the subfields of public economics as “structure and scope of government; taxation, subsidies and revenues; fiscal policies and behaviour of economic agents; publicly provided goods; national government expenditures and related policies; national budget, deficit and debt; state and local government; intergovernmental relations” (American Economics Association 2006, pp. 1157–1158).

The public choice tradition, associated with the economist James Buchanan, sees government as a collection of rational, self-interested agents. These agents trade and exchange in the public sector, just as firms and consumers do in private markets. Central concerns of public choice include the behavior of bureaucracies and the design of political institutions, including constitutional rules. Although public choice is an avowedly positive research program, it has normative implications. For example, a positive statement that bureaucrats attempt to maximize the size of their budgets thereby extracting all benefits from government activity has implications for how large governments should be. Public choice has had a major influence on current political science research, and this intersection between economics and politics is frequently referred to as political economy.

In the twenty-first century the borders between public economics and other areas of economics have blurred, as has the division between the public finance and public choice traditions. Since government impacts all aspects of the economy, economists in other fields also study the public sector. For example, labor economists study the effects of taxation and income support programs on labor supply, environmental economists study the problem of externalities, and so on. In the later part of the twentieth century the size of government in industrialized countries stabilized or shrank, while economists became aware that governments, like markets, could fail. Public economists began to study nongovernmental forms of collective action, for example, the private provision of public goods. The central insight of public choice, that politicians and bureaucrats are rational—and not necessarily benevolent—agents, became widely accepted. The Journal of Public Economic Theory describes the scope of contemporary public economic research in its mission statement: “public goods, local public goods, club economies, externalities, taxation, growth, public choice, social and public decision making, voting, market failure, regulation, project evaluation, equity, and political systems” (“Aims and Scope”). Public economics is no longer simply the economics of the public sector.

ECONOMICS, STRATIFICATION
Stratification economics is an emergent subfield of economics that uses the concept of social stratification as a point of departure for examining structural and intentional processes that generate hierarchy and economic inequality among groups whose members are defined by one or more characteristic or attribute. Social stratification typically refers to the hierarchical arrangement of social classes, castes, and strata within a society. Stratification economics analyzes the social processes influencing the nature and reproduction of stratification not only within, but also across, different societies. Within stratification economics, special attention is directed to the role of racial and caste distinctions and similar group affiliations in producing and perpetuating income and wealth inequality.
Stratification economics treats group identities as produced forms of individual and collective property with both income and wealth-generating characteristics. In addition, these groups' supply and demand are responsive to changes in production costs and budget constraints. Cooperative economic and noneconomic behaviors are treated as normal outcomes of individuals' propensity to engage in own-group altruism and other-group antagonism. Theoretical stratification-economics models predict that a person's reward for cooperative behavior increases with the mean wealth of the person's group, so that income and wealth inequality strengthen incentives to engage in cooperative behavior.

Within stratification economics, an individual has constrained choices among various identities, such as racial classification and nationality, which establish the foundations for intergroup conflict. For example, powerful groups often attempt to create property rights that facilitate the exclusion and exploitation of nonmembers and provide privileged access to private and public goods for members of the dominant group. Such rights are maintained by social custom, history, law, and other means. Ascriptive markers such as skin color serve as signals to dominant interests to vary the intensity of discrimination targeted at particular subordinate individuals and groups. For example, during the era of slavery in the United States, lighter-skinned blacks were often afforded more privileges than their darker-skinned counterparts, while still encountering discrimination.

Theoretical stratification economics challenge conventional wisdom about the dynamics of intergroup inequality. Stratification economists argue, for example, that intergroup conflict in both economic and noneconomic settings is an endogenous characteristic of the social space, rather than an exogenous contaminant of market allocation processes and individual decision-making. Reductions in intergroup equality and income will not automatically lead to the erosion of traditional patterns of collective identification if the expected returns to additional investments in group identity are unequal across groups. Movement toward more egalitarian intergroup distributions of wealth must therefore be a major element in any earnest attempt to reduce intergroup conflict, because inequities are institutionalized through processes that enable the transfer of material resources across generations.

Stratification economics is supported by studies of mechanisms perpetuating domination in various countries including white privilege in the United States and throughout the Americas, high-caste Hindu privilege in India, and Protestant privilege in Northern Ireland. Studies of economic discrimination targeting particular subgroups in various market societies, including African Americans in the United States, the Buraku in Japan, East and West Indians in Britain, and blacks in Canada, also provide useful insights for stratification economists.

As stratification economics evolves, it is likely to pose increasingly robust challenges to schools of thought that emphasize group-based deficits in personal responsibility and cultural practices as the primary sources of persisting intergroup economic inequality.

**ECONOMICS OF CONTROL**

The *economics of control,* perhaps best represented by Abba Lerner's (1903–1982) 1944 book of that title, based on his 1943 doctoral dissertation for the London School of Economics, is a halfway-house policy approach to capitalist economies between laissez-faire on the one side and socialist economic planning on the other. The economics of control accepts the basic institutional framework of capitalist markets as the organizing principle but recognizes market imperfections, macroeconomic deficiencies, and other problems that require government intervention to improve market outcomes. It was an attempt, in the
the words of Sidney Ratner (1908–1996), at a “reconciliation of liberalism and socialism in welfare economics” (Ratner 1949, p. 133).

John Maynard Keynes (1883–1946), in a letter written at sea on a voyage to the United States during which he read The Economics of Control, wrote to Lerner that the latter had “written two books largely distinct … which you have placed within one cover” (Colander and Landreth 1996, p. 116). The first was dedicated to microeconomic problems analyzed through the neoclassical marginalist approach but infused with a spirit of market socialism that Lerner described as “socialist free enterprise.” This work was part of the debate on socialist planning that has often been viewed as dealing with the question of the viability of a socialist economy but really concerned a more specific, technical issue: whether or not neoclassical theory, in particular general equilibrium analysis, was applicable to a planned economy. Friedrich August von Hayek (1899–1992) and the Austrians said no; Lerner, Oskar Lange (1904–1965), and others claimed that it was (Kirzner 1988).

The second “book” covered macroeconomics and Keynesian theory, which included demonstrating the theoretical justifications for employing Lerner’s functional finance approach. This approach implied strong fiscal and monetary policies for promoting macro goals, such as full employment, price stability, and stable economic growth, not only for their own sake, but also because full employment was seen as a precondition for the relatively smooth workings of the microeconomy. Keynes called this “second of the two books which you have placed within one cover … very original and grand stuff,” adding:

I shall have to try when I get back [to England, from his trip to the United States] to hold a seminar for the heads of the Treasury on Functional Finance. It will be hard going—I think I shall ask them to let me hold a seminar for their sons instead, agreeing beforehand that, if I can convince the boys, they will take it from me that it is so! (Colander and Landreth 1996, pp. 116–117)

Keynes does not trust that the heads of the Treasury can understand, because, as Lerner often noted, “Functional Finance is seen to run counter to economic principles” (Lerner 1951, p. 142). Functional finance, or Keynesian economics taken to its furthest logical conclusions (causing David Colander to ask, “Was Keynes a Keynesian or a Lernerian?” [1984]), was, in its application to unemployment, Lerner admitted, “topsy-turvy economics”: “But this is no objection at all. Topsy-turvy economics is just what is appropriate for an economy that is suffering from unemployment. An economy suffering from unemployment is an upside-down economy for which only a topsy-turvy economic theory is of any use” (Lerner 1951, pp. 142–143).

By an “upside-down economy,” Lerner means an economy in which strongly held traditional economic principles, such as those regarding thrift and the economic use of scarce resources, do not hold. Lerner noted that when there is unemployment, efficiency becomes inefficient: “an increase in efficiency in any particular productive process does not result in any increase in efficiency in the economy as a whole. … The savings due to greater technical efficiency merely go to waste in more unemployment” (Lerner 1951, pp. 143–144). Likewise when there is unemployment, a country has to suffer over its trade balance, because it must worry about rising unemployment stemming from an increase in the value of its imports over the value of exports. Since “the input of the foreign trade industry consists of the effort involved in the manufacture of our exports” and “the output of our foreign trade industry consists of the imports which it yields to us for our use,” exports are a cost and imports are a benefit (Lerner 1951, p. 321). Thus when a nation attempts to cure its unemployment problems by reducing its trade deficit, it is promoting costs and restricting benefits.

Other supporters of the economics of control went beyond what they viewed as Lerner’s approach, made up as it was between neoclassical welfare economics on the one side and traditional Keynesian fiscal and monetary policies on the other. Adolph Lowe (1893–1995) made the distinction between primary and secondary controls (Lowe [1965] 1977). Primary controls, or conventional economic policies, take the behavior of the microunits as given, whereas secondary controls, or what Lowe sometimes called instrumental controls, seek to shape the behavioral patterns of the microunits themselves, either directly or through creating the structural or environmental contexts that can influence motivations and behaviors (Lowe 1969, p. 33). Examples of the former include a variety of fiscal and monetary policies. The latter would be exemplified by policies that shape expectations (e.g., reducing uncertainty). The line between the two is not always clear, because fiscal and monetary policies can also influence expectations. If business investors know that the state is committed to maintaining a high, stable rate of growth of demand, they will have less uncertainty about future conditions that affect investment and thus output and employment. As Lerner noted, the purpose of taxation is its “effect on the public of influencing their economic behavior” (Lerner 1951, p. 131).

ECONOMIES, TRANSITIONAL

The breakdown of centralized socialism in the Union of Soviet Socialist Republics (USSR), Central and Eastern Europe, and Asia at the end of the twentieth century resulted in the adoption of the market process as a means of organizing the economy. The movement from a centralized socialist economy to an economy based on market relations has been termed transition and thus the economies that have adopted this process are called transitional economies. In particular, the transition process was associated with an explicit end-state, namely the establishment of a capitalist economic system. Hence, the transition involved, in essence, the introduction of private ownership and restructuring through the privatization of state enterprises; the establishment of market equilibrium through the abolishment of centrally administered commands; the liberalization of economic activity through institutional reform; a change in economic behavior as a result of economic actors adjusting their behavior in line with self-interest and the rules of market exchange; and the reduction of the state to the role of legislator and facilitator of economic activity.

The term transition has been criticized as being inadequate, however, because it does not capture all the complications involved during the process. The term implies a linear movement from point A (centralized socialism and disequilibrium) to point B (capitalism and equilibrium). Specifically, because transition implies an end-state, the achievement of that end-state completes the whole process. It can thus be argued that the process is already complete, for the transition economies have in fact established a capitalist economic system and most of the countries of Central and Eastern Europe are members of the European Union. In this view, the term transitional economy is obsolete.

It can also be argued, however, that the “transition” process is continuous, and that equilibrium can never be achieved. This has led to the use of terms such as transformational economy and developing economy. In addition, capitalism comes in many varieties, so the question of what type of capitalism should be the goal complicates the process (Marangos 2004). Some commentators have also questioned the goal of achieving a capitalist economic system, with alternatives such as market socialism being proposed as the most appropriate economic system. China and Vietnam are examples of this type of system. Lastly, an alternative term, “integration-assisted transition,” has been introduced by Aristidis Bitzenis and John Marangos (2007), who argued that the goal of transitional economies was the participation in the globalization process and attempting to integrate their economies into the globalized system by opening their borders, liberalizing their markets, and attracting foreign direct investments with the assistance of international financial institutions and multinationals.

The economic program of transition involved four elements. The first was macroeconomic stabilization, which reduced inflation and decreased the debt burden. The second was the liberalization of economic activity, including prices, trade, currency, and convertibility. The third was the reduction of the size of the public sector through privatization and the restructuring of state-owned enterprises. The last element was the establishment of new laws and regulations in areas such as property rights, corporate law, accounting practices, and tax regulation. It is clear, then, that the decision to move to a market-based economy required a total transformation of the economy. Meanwhile, the citizens of these countries were unprepared to face the economic adversity and uncertainty resulting from the free-market process, mainly because they had been protected for so long by the Socialist State.

Although all the countries in transition had more or less the same final goal, the results of their efforts are diverse. This is because different strategies, policies, paths, and conditions ensured a variety of transition processes and outcomes (Bitzenis 2007).

**EDUCATION, INFORMAL**

Informal education refers to intentional educational encounters occurring beyond the classroom. Many learning experiences are random and accidental; however, informal education, although it may flow from chance encounters or fortuitous events, embodies an element of premeditation. Certainly informal educators, like their compatriots operating in schools and colleges, consciously set out to promote learning and impart skills. They are teachers and like all teachers will plan, evaluate, and reflect upon their teaching. Clearly some overlap exists with experiential learning, since informal educators may also create opportunities for learning. However, the key difference between the two is that informal educators predominately work via the conversation that emerges from reflection on the daily experiences of the individuals and groups rather than the analysis of experiences initiated by the facilitator and educator (see Warner Weil and McGill 1989).

The first text to deliberately employ the term was *Informal Education* (1946) by Josephine Macalister Brew (1904–1957). However, such essentially unstructured education, characterized by spontaneity and built upon the interplay inherent in dialogue and conversation, clearly has a long history. Possibly predating the formal variety, unstructured education flourished in ancient Athenian society (Jeffs 2001). There it stood apart from rote learning and instruction as the accepted way whereby individuals acquired social skills, an understanding of the arts, and appreciation of matters philosophical and spiritual.

Although it is important to avoid minimizing the commonalities between teaching in the formal and informal sectors, crucial differences do exist. First, informal educators predominately operate via the medium of conversation and dialogue. Unlike the formal sector, where the curriculum and syllabus mold the educational encounter, here content emerges from conversational encounters. Informal educators consciously engage in conversation with the purpose of fostering learning, intentionally encouraging others to clarify their thinking, formulate their ideas, and articulate learning needs. The objective is to cultivate dialogue that will enable both parties to learn from and better understand each other (Jeffs and Smith 2005).

Second, informal education is based upon a voluntary relationship. Even within such institutions as prisons or schools, where attendance for one party is compulsory, informal educators strive to ensure those engaging with them do so freely.

Third, informal education requires the practitioner to operate where people are. They need to be “around” and “accessible.” Therefore they must either work in settings they do not control, such as schools and the “street,” or establish sites, such as settlement houses, youth clubs, and community centers, that provide services, programs, or activities that individuals and groups will seek out. For example, those operating in schools work the public spaces, such as hallways and canteens, in ways that enable students and staff to engage them in conversation (see Hazler 1998). In the clubs, community centers, and settlements, informal educators make time between and in activities for users to engage with them (see Hirsch 2005). They also create social spaces in these buildings where conversation will naturally occur. Those operating on the “street” usually target “hot spots” where, for example, young people or the homeless gather. Irrespective of the environment, informal educators draw upon a repertoire of skills to enable them to make contact and develop relationships. This means they must improvise and think for themselves. To be successful, practitioners must, as Brew (1946) stressed, be interesting and trustworthy people with whom others will freely spend time. Also they must be sensitive to the social and cultural environment they operate within if those they work for are to respect their judgment and opinions. Simply being “around” is never enough.
Overall, what distinguishes informal education is not its role and purpose, as generally these approximate those encountered elsewhere. Rather, it is the location and modus operandi of the educator. Although largely associated with youth work, settlement houses, and community work, informal education has noticeably been adopted as a means of intervention by a wide range of agencies since the 1980s (Smith 1988; Jeffs and Smith 1999). Notably, health and criminal justice agencies have looked to informal education as a means of reaching groups and individuals resistant to their message. Sadly, the repertoire of skills developed by informal educators is often employed merely to deliver a packaged message, and the underlying commitment to dialogue and shared learning is set aside. This incorporation of elements of formal practice, notably in the United Kingdom and United States, has led to attempts to create an informal education curriculum and undertake the assessment of learning outcomes from “informal education” encounters (see Ord 2004). Unfortunately such accreditation is based on a profound misunderstanding of the informal education process: a naive assumption that because curriculum-led learning is taking place in clubs and centers, it is not formal education. This view overlooks the reality that formal and informal education can operate side by side yet remain discrete entities. Venue is not the defining characteristic; rather, it is whether or not the intervention is curriculum or dialogically led.

In parts of Europe aspects of informal education are frequently designated social pedagogy. The two are not synonymous but share many characteristics and historical antecedents.

EDUCATION, RETURNS TO

There is a strong consensus among economists that education is one of the key determinants of people’s earnings. According to the human capital theory, education is an investment that increases the market skills and productivity of individuals who undertake it. Consequently, these individuals earn higher wages in the labor market for higher skills and productivity. While monetary returns to education take the form of higher earnings that people command in the labor market, there may also be nonmonetary returns since higher education is often associated with psychic gains, such as increased respect from others.

Like any other investment decision, investing in human capital through education entails costs that are borne in the short term with the expectation that benefits will be captured in the long term. Since the returns to education will not accrue for some time, the theory predicts that present-oriented individuals are less likely to invest in education than forward-looking individuals and that younger individuals will be more likely to invest than older individuals.

The question of whether returns to education are high enough to justify the costs of additional education is an important question, not only for individuals but also for policymakers. It is often argued that government policies can improve the economic well-being of the poor by subsidizing their education, offering loans for college students, and imposing minimum education requirements.

It is important to make the distinction between the private and social rate of returns to education. The private rate of returns to education is the increase in the earnings from an additional year of education for an individual who makes the investment decision on education, while the
social rate of returns to education measures the increase in
national income resulting from the same year of education
(Borjas 2004). It is often the social rate of returns to edu-
cation that provides a basis for government programs, such
as scholarships and education loans that are aimed at
increasing the levels of education of individuals.

Numerous studies suggest that the rate of returns to
education in the United States was around 9 percent in
the 1990s (Borjas 2004). The rate of returns to education
varies from individual to individual due to differences in
age, ability, quality and quantity of education, and socio-
economic status. For example, it is often assumed that
more able individuals benefit more from an additional
year of education. Also, better-quality education is likely
to enhance the productivity of individuals by improving
cognitive skills, thereby increasing the rate of returns to
education. It is also assumed that the rate of returns to
education is a decreasing function of the quantity of edu-
cation. In other words, the additional earnings generated
from an extra year of education are likely to be higher for
people with low levels of education than for those with
high levels of education.

The rate of returns to education may also vary
between individuals from different races, ethnicity, or
gender due to discrimination. However, the empirical evi-
dence on this is mixed. On the one hand, studies by Pedro
and Christopher Taber (2001) show that the return to
education is greater for more able individuals. On the
other hand, Orley Ashenfelter and Cecelia Rouse (1998)
find some evidence that the rate of return may be even
higher for individuals coming from more disadvantaged
backgrounds, and Lisa Barrow and Cecilia Rouse (2005)
find that returns are similar for African Americans,
Hispanics, and whites. The large disparity in education
levels between different racial and ethnic demographic
groups is considered to be a major reason for the observed
inequality in the distribution of income and wealth in the
United States. While increased educational opportunities
for minority groups will certainly help narrow these
inequalities, they are likely to be most effective only if
coupled with policies that are aimed at eliminating the
barriers to equal access to education for these groups.

The typical method for estimating the rate of returns
to education requires data on the earnings and levels of
education of different individuals, along with estimations
of the percentage change in earnings associated with an
additional year of education. This formulation is often
called the Mincer earning function, named after Jacob
Mincer (1922–2006), one of the pioneers of modern
labor economics.

When estimating the rate of returns to education, it
is important to adjust for all other differences in individ-
ual characteristics in the data, such as ability, race, ethnic-
ity, gender, and age. A failure to adjust for all these dif-
ferences will result in bias in the estimated rate of returns
to education. However, the empirical difficulty of appropri-
ately accounting for these differences constitutes an
important challenge for researchers studying the returns
to education. While characteristics such as age, gender,
and race are readily available in most data sets, the ability
levels of individuals are seldom observed in these data. It
may be true that more able individuals are likely to obtain
more years of education than others because it is easier for
them to do so. Therefore, these individuals are likely to
have higher earnings. However, such individuals may also
earn more than others simply because they are more pro-
ductive regardless of their levels of education. In other
words, higher-ability individuals may earn higher wages
than lower-ability individuals with equal levels of educa-
tion. Therefore, a study not taking into account the differ-
ences in ability across individuals will result in a biased
estimate of the rate of returns to education.

The discussion above assumes that education
increases individuals’ earnings by raising their produc-
tivity. An alternative argument is that education can increase
earnings even if it does not make individuals more pro-
ductive. According to this view, education mainly serves as
a signal about the qualifications of the workers to poten-
Employers, especially in situations where they cannot eas-
ily observe the abilities or productivity of workers, may
rely on education as a signaling device in their hiring deci-
sions. As far as the private rate of returns to education is
considered, it may not matter whether it is the productiv-
ity or the signaling model that represents a correct picture
of the education and earnings relationship because educa-
tion is positively linked to earnings under either scenario.
However, if the signaling model is the correct link
between education and earnings, society will not benefit
from increased education. In this case, the social rate of
return to education will be zero.

EDUCATION, UNEQUAL

In the social sciences, education is recognized as playing a central role in maintaining and reproducing modern systems of inequality. Hierarchies of race, class, and gender are understood to be reflected in both the content of educational offerings and in the context in which schooling is provided. As such, attempts to address patterns of social inequality have focused on improving educational access and conditions for various populations. In the case of the twentieth-century United States, efforts to equalize access to schooling along lines of race and class have drawn heavily upon the insights of American social scientists, while responding to the demands of both liberal and conservative political constituencies.

Despite residing in communities where they often represented significant parts of the population, blacks and other racialized minorities often possessed little or no ability to control their educational destinies—not in choice of curricula, the hiring and firing of teachers, nor the availability of school facilities or the length of the school term. Long practiced by custom in many localities and written into state constitutions in the decades following the American Civil War, racial segregation in schools was given legal mandate in the U.S. Supreme Court’s ruling in

Plessy v. Ferguson (1896), out of which came the doctrine “separate but equal,” which allowed states effectively to separate access to educational resources on the basis of race as long as those provided to each racial group were equal. After some sixty years of state-mandated racial segregation in education, during which blacks and other minority populations lagged behind whites on most indicators of educational progress, the U.S. Supreme Court, heavily influenced by the findings of social scientists, decided unanimously in

Brown v. Board of Education of Topeka, Kansas (1954) that the practice of segregated schooling was not only unconstitutional but also inherently damaging to children, with dire effects for society as a whole. While the Brown decision has generally been viewed as a landmark development in the struggle to dismantle racial inequality in American education and society at large, it was in many ways limited. The court’s rulings were unendorsed, loosely defined, and, by some accounts, underfunded as a federal mandate for public schools. Institutionalized resistance by southern states prevented full implementation of the court’s rulings until 1968, when schools in the rural South were given a mandate that they must desegregate in order to be in compliance with federal law. Additionally, because of the Court’s focus on de jure segregation common in the South, the de facto segregation that had been practiced in the northeastern and midwestern states remained largely intact until the 1970s, when concerns were expressed about the education of minority schoolchildren in such cities as Pasadena, Chicago, San Francisco, and Boston.

The Brown ruling and the subsequent reexaminations of the American educational system it inspired called attention to the complex intersections of race and class in American education and their effects on academic achievement. The Elementary and Secondary Education Act of 1965, which provided additional federal monies to schools with a significant proportion of poor or disadvantaged students, grew out of the concerns expressed in Brown. Perhaps one of the most influential works of social science research in the immediate post-Brown era was James Coleman’s Equality of Educational Opportunity (1966), sponsored by the U.S. Department of Health, Education, and Welfare and commonly referred to as the Coleman Report. The study’s specific purpose was to evaluate indicators of educational opportunity among white and minority students (blacks, Puerto Ricans, Mexican Americans, Asian Americans, and Native Americans) by assessing educational quality in terms of the availability of curricula, school facilities, academic practices, and the academic characteristics of teachers and student bodies in schools. Among Coleman’s chief findings were that while persistent and unequal separation by race was found to be detrimental as per the Supreme Court’s ruling in Brown, it was the combination of the socioeconomic composition of the school, the familial and socioeconomic background of the students, and the nature of their peer groups that accounted for the majority of the differences observed in academic achievement between white and minority schoolchildren. Racial integration alone, Coleman and his associates concluded, could not improve the academic performance of poor minority children.

In a context where explanations for patterns of social inequality favored concepts of “cultural deprivation” among poor and minority communities, the report’s widely cited findings proved to be controversial. Commentators recognized that schools in and of themselves were limited in their power to change society at...
large. Conservative critics of educational reform argued that social science research had justified their resistance to increased educational spending for underachieving populations. They argued that this underachievement was the result of a “cultural mismatch” between schools and targeted populations. Others, such as Jencks et al. (1972), noted that only by addressing the underlying economic causes of race and class inequality could patterns in education be remedied. Ultimately, federal educational policies continued to favor funding compensatory programs such as Head Start and remedies such as busing under the assumption that they would address the twin problems of differentials in academic performance and differential access to educational resources among minority and poor schoolchildren. In addition to encountering resistance from various segments of the population, these programs received mixed reviews of their long-term effectiveness, and the persistence of the gap in educational achievement for much of the 1970s continued to trouble reformers and policymakers. This period witnessed a resurgence of Marxian analyses of education, which focused on the role of schools in maintaining the class structure of capitalist societies. Neo-Marxist works contend that educational systems not only expand in response to economic shifts but also chiefly serve to reproduce a large class of workers by stressing obedience to authority and contentment with one’s place in the system. Critiquing this view as a “black box” perspective in which class is assumed to be reproduced through schooling, cultural sociologists such as Willis, Bourdieu, McLeod, and Oakes further elaborated on this work by examining strategies of social reproduction as they take place in everyday school interactions. These include academic sorting, interactions between students and school personnel, interactions among peers, and the general culture of the school.

The 1980s marked what some consider the end of “liberal hegemony” in American education and ushered in the neoconservative turn in educational reform. The publication of *A Nation at Risk*, which cited generally lower rates of performance among American schoolchildren and a persistent achievement gap by race and class as proof the failure of liberal reform, served as a manifesto for conservative reformers. Influenced by the findings of the Coleman Report and other studies that took a dim view of compensatory education, neoconservative reformers sought to remedy race and class achievement gaps through what they described as a focus on “standards and accountability” and an application of market forces to education. Under the administrations of Ronald Reagan and George H. W. Bush, federal support for compensatory educational reforms diminished drastically and school districts were released from court-imposed plans for achieving racial balance without, as Orfield notes, having done so. Rather than continuing to search for solutions for failing schools through expensive government programs, the parents of poor and minority schoolchildren were encouraged to exercise their rights as consumers of public education and to improve their educational prospects by leaving failing schools and choosing those schools (whether public, private, or charter) with demonstrated levels of achievement.

The neoconservative influence in educational reform continued under the Clinton administration, during which the Improving America’s Schools Act (Public Law 89-10) was passed. While reauthorizing the Elementary and Secondary Schools Act of 1965, the 1994 act also endorsed the establishment of charter schools as a means of improving teaching and student performance. This pattern of reform greatly expanded under the presidency of George W. Bush in the form of the No Child Left Behind Act (Public Law 107-110). Signed into law by the Bush administration in 2002, NCLB’s expressed goal was to close the persistent race and class gap in educational achievement. While supporters of the act pointed to the implementation of much needed standards and timelines for schools to measure progress and make improvements and the ability of parents to choose better schools for their children, critics maintained that the act severely limited the means by which schools can effect those improvements. Rather than increasing the amount of federal support for public education, the act applies strict legislative guidelines for the use of Title I funds that limit curricular innovation in favor of an emphasis on “basic” subjects such as reading and mathematics, a mandate that schools meet state-determined measures of annual yearly progress, and, as a means of assessing student performance, the use of high-stakes standardized testing on which poor and minority students typically score lower. Many schools argue that by imposing a rigid framework and encouraging poor and minority parents to abandon neighborhood schools for better equipped, higher-scoring schools in affluent neighborhoods, the achievement gap will persist by encouraging individual rather than group mobility.

The American educational system’s foundations as an unequal system rooted in hierarchies of race and class have both inspired and limited attempts at reform that seek to remedy the long-term effects of these inequalities. Over the course of the twentieth century, social scientific considerations of educational inequality have shifted from a belief that schools are the sources of social difference with the capacity to fundamentally change society to the more critical understanding that schools have powerful effects in society but are limited in their ability to effect change through social engineering. The current body of social science literature on education focuses on the role that schools played in reinforcing and legitimizing hierarchies of race and class through a variety of means, including, but not limited to, curricular choices, school cultures, pat-
terns of organization, and policies governing school funding.

EDUCATION, USA
The most universally recognized function of schools is to impart knowledge and skills that will enable the learner to participate successfully in a society’s institution (Epps 1995). As early as the 1920s, social policy became directed toward using elementary education to further children’s social and emotional adjustment outside of the home. Recognizing that educational training in the early years of human development was essential for enhancing cognitive skills, reinforcing social norms, and preparing youth for participation in the labor market as adults, educational policy in general, and the public school system in particular, aimed to train youth to become productive citizens.

During the early part of the twentieth century, various administrative progressives, philanthropic associations, and civil rights organizations (to a lesser degree) played an integral role in shaping educational opportunities. The chief architects of educational policy were an elite group of white men that consisted of city superintendents, education professors, state and federal officers, leaders in professional organizations (i.e., the National Education Association), and foundation officials (Tyack and Cuban 1995). These men provided the blueprint for an educational institution mandating criteria for schooling, differentiating curricula according to students’ career paths, standardizing the structure of schools in order to provide uniform staffing and social and health services, and overseeing the regulation of educational practices. Moreover, the Carnegie and Rockefeller foundations, the General Education Board (which helped to develop black education in the Jim Crow South), and various civil rights organizations (i.e., the National Association for the Advancement of Colored People) provided financial support, developed curriculum, and trained educators with the hopes of creating an equitable educational system. Although the institution of education aimed to provide youth with a solid foundation for the future, the separation of blacks and whites into different and inherently unequal educational institutions created a system that reflected economic and social inequalities.

To the creators of these institutions, educational attainment was considered the panacea for social inequality. However, due to the racial order and quality of schools, blacks lagged behind whites on all indicators of performance. Research providing explanations for these differences was biologically deterministic. Critical studies that addressed educational inequalities and the problem of race/ethnicity coincided with the racial order; variations in performance were attributed to innate differences in cognitive ability.

From the 1920s to the 1950s, the educational opportunities of blacks were shaped by popular discourse characterizing blacks as intellectually inferior. The genetic interpretation of race and research on the inheritability of intelligence influenced the types of learning materials afforded to segregated schools and shaped conclusions about black youth (Anderson 1988). Moreover, Jim Crow education was designed, implemented, and upheld by the state. As a result, for over thirty years, the majority of blacks attended substandard schools, primarily in rural areas or in the South, which often lacked the most basic
Education for learning such as textbooks, slates and chalk, desks, had relatively small classes, and were taught by instructors without postsecondary training (Tyack and Cuban 1995).

Some early sociological studies argued that the various components of the educational system were disconnected and that the system could not cure the social ills of society as originally believed. Willard Waller (1932) conceptualized schools as unstable social systems in which different components—administrators, teachers, parents, students, and community groups—all with competing interests, vie for power and authority. Scholars did not address the question of how the convoluted structures of segregated schools further increased social inequality for black students or attempted to understand why a significant proportion of this population remained poor and socially immobile. The first sociologist to conceptualize a theoretical framework that attempted to solve the “race problem” was Robert Park (1950), who examined how ethnic groups acculturate into American society through contact, competition, accommodation, and eventual assimilation. Park’s work, however, focused solely on white ethnic groups (i.e., Irish or German immigrants), and the assimilation of blacks and the racial problems that thwarted their progress were not addressed. At the same time, various contemporary empirical studies of educational achievement and motivation reinforced the notion that better performers had higher drives, and implied that racial variations in performance resulted from a lack of motivation on the part of black students.

Not until school segregation was challenged by the landmark case Brown vs. Board of Education (1954) was attention given to the detrimental effects of separate and unequal educational institutions on the academic achievement of black students. This case, which desegregated K–12 education, forced empirical studies to look toward structural inequalities as the culprit for disparities in performance, as opposed to lack of motivation or biologically deterministic explanations. Empirical studies provided evidence that racial/ethnic differences in achievement were associated with differences in socioeconomic status (Rosen 1959).

During the 1960s civil unrest, government emphasis on alleviating poverty, and black political mobilization brought new attention to the ways in which inequality undermined educational attainment for blacks. As part of national efforts to alleviate poverty, President Lyndon B. Johnson created Title I programs targeting funds to students from low-income families to prevent poverty from restricting school opportunities and academic achievement. Also, the 1965 civil rights act, executive order 11246, called for vigorous, proactive steps, later termed affirmative action, to broaden and increase access to higher education for previously excluded and underrepresented groups (Allen et al. 2002).

In addition to policies mandated to improve educational access and quality, research studies examining racial differences in academic performance received much funding. Among several empirical studies investigating the relationship between inequality and educational attainment, a 1966 report by James S. Coleman was the most influential. It demonstrated that family background had a significant effect on academic achievement and that schools played a role in creating and sustaining student differences in achievement. Moreover, the Moynahan Report (1965) presented a cultural argument for educational inequality that did not rest on IQ differences but on the attitudes, time perspectives, family patterns, and values of the poor. Samuel Bowles and Herbert Gintis (1976) provided further evidence that poor school quality was a predictor of limited economic success and viewed schools as an instrument used by the dominant class to maintain the status quo.

Contrary to earlier studies of educational attainment that emphasized biologically deterministic explanations for performance, educational research in the 1970s and 1980s took a more holistic and liberal approach. Scholars consistently showed that race and ethnicity, along with socioeconomic status, were significant determinants of educational and occupational success; that stratification processes worked differently for students from various backgrounds; and that schools could depress the relationship between background and occupational attainment by providing more equal access to educational resources and training (Hallinan 2000). Much educational research since the 1980s has sought to identify the problems associated with educational inequality and outcomes and has focused on implementing strategies to decrease racial gaps in academic achievement. However, some argue that the approaches employed have actually increased educational disparities rather than alleviating them.

PRESENT-DAY PROBLEMS AND PROSPECTS

Despite various policies aimed at reducing educational inequality, such as the Brown decision of 1954, educational opportunity programs created in 1965, and Affirmative Action of 1964, the educational system at the start of the twenty-first century—more than forty years after the civil rights movement began—still remains segregated by socioeconomic status (SES) and race/ethnicity. For students that come from more affluent families with high levels of social capital, the educational system serves to adequately prepare them for competitive jobs in the labor market. Conversely, for students with low SES and limited resources, the educational system has failed to pro-
vide the needed foundation and skills to sustain an adequate lifestyle. Most importantly, minority students—namely, blacks and Hispanics—are overwhelmingly overrepresented in the lower SES category and attending schools that are substandard in terms of instruction, curricula, socialization practices, preparation for the job market, and providing equal access to higher education opportunities.

Disparities in educational achievement are evident in the early years of primary school, where blacks and Hispanics lag behind whites and Asians on several indicators of educational achievement. Table 1 illustrates the percent distribution by race and ethnicity of mathematics achievement levels for a representative sample of students taking the National Assessment of Educational Progress (NAEP) exam in 2003. As can be seen, 46 percent of black and 38 percent of Hispanics performed below the basic levels of achievement for fourth graders. Moreover, differences in achievement levels worsen as students advance to higher grades (as measured by the performance of eighth graders).

Table 2 illustrates the percent distribution by race and ethnicity of achievement levels on reading comprehension tests for a representative sample of students taking the NAEP in 2003. Results show that 60 percent of blacks and 56 percent of Hispanics are below basic fourth-grade reading levels compared to 25 percent of whites. Although performance in reading improves for blacks and Hispanics by the eighth grade, disparities in performance between racial groups remain constant. Contemporary research examining racial differences in educational achievement in primary and secondary education indicates that the gap continues to widen as students advance to higher educational levels (Steele 1997).
The next section examines some of the structural obstacles that limit educational attainment for minority students (i.e., blacks and Hispanics) and may account for racial/ethnic variations in academic performance.

**RESIDENTIAL SEGREGATION, INSTITUTIONAL INEQUALITY, AND EDUCATIONAL OPPORTUNITIES**

Due to the history of racial stratification in the United States, blacks and whites reside in neighborhoods that are economically, socially, and racially distinct from one another (Jargowsky 1996; Massey and Denton 1996; Massey 2004). Although structural barriers that prohibited residential mobility for minorities have been removed in the post–civil rights era, the historical vestiges of exclusionary practices that were and continue to be pervasive have implications for the racial formation of more recent residential patterns. As a result, minority integration into diverse neighborhoods has been slow to nonexistent. Research has shown that blacks remain the most segregated racial group (Massey and Denton 1992), even when factors such as neighborhood preferences (Farley et al. 1978; Zubrinsky and Bobo 1996), racial attitudes and stereotyping, and preferred educational level of neighbors (Benabou 1992; Cutler and Glaeser 1997) are taken into account. Residential patterns for Hispanic families are very similar to those of blacks.

Residential segregation is a mechanism that has historically perpetuated systemic inequality and is mainly responsible for inequality in primary and secondary education. Two-thirds of urban blacks live under conditions of high segregation and two-thirds attend minority-dominant public schools (Massey 2006). Considerable research documents the disadvantaged conditions experienced by blacks in segregated schools, such as limited spending on students and curricula, and a lack of qualified teachers (Anderson and Byrne 2004). Since American schools are funded by local property taxes, the wealthiest districts spend as much as three times per-pupil compared to the most economically disadvantaged districts (Dion and Roscigno 2003). Although schools that are located in lower-SES communities may receive additional funds from federal Title I programs, these schools normally spend a sizeable majority of their budgets on repairs, maintenance, and structural improvement of school buildings. Compared to low-SES segregated schools that primarily educate black and Hispanic students, high-SES schools that are predominantly white spend more on instructional materials and provide higher pay for teachers. As a result, low performing students are less likely to get placed into vocational tracks, are better prepared for postsecondary education, and receive the skills necessary to acquire competitive jobs. Consequently, for minority students that attend public schools in residentially segregated neighborhoods, institutional quality has negative implications for educational outcomes. Teachers’ expectations are lower, and minority students are more likely to be placed in lower tracks (vocational vs. honors/college preparatory) by their instructors, more likely to have lower reading and math scores compared to the national average, and are less likely to attend four-year colleges and universities (Oaks and Guion 1995; Allen et al. 2001; Dinwiddie and Allen 2003). Recent sociological research has shown that improved education (as a result of money spent on curricula, the hiring of qualified teachers, and providing access to resources) is a strong predictor of academic achievement, which contradicts culturally deterministic theories that claim minorities do not value education (e.g., the popular “acting white assumption”).

School districts and the federal government have recognized that public schools provide different levels of educational preparation for their students. Therefore, in an effort to provide options, various voucher systems and school-choice policies have given parents the opportunity to take advantage of schools that are known to better educate children (i.e., magnet and charter schools). Magnet-school programs allow public school students to leave their neighborhood schools to attend specialized institutions that offer unique curriculums. Thirty-four percent of the nation’s school districts have magnet-school programs, making magnet-school choice one of the most widely used forms of school choice in the country (Saporito 2003). However, students must qualify based on test scores, grades, behavior, and other criteria that are evaluated by teachers from their neighborhood schools. A problem with magnet schools and the voucher system is that there are many more applicants than openings and school districts are prohibited from taking race or ethnicity into account when deciding which students to admit.

**CURRENT POLICY ADDRESSING EDUCATIONAL INEQUALITY**

Educational reforms have been the preferred methods of addressing educational inequalities (Tyack and Cuban 1995). One contemporary approach that has received much criticism is No Child Left Behind (NCLB). President George W. Bush’s effort to renew the Elementary and Secondary Education Act of 1965. The NCLB law requires yearly standardized testing of students from kindergarten to eighth grade in reading, language, and math and holds schools accountable for meeting state and district goals. It also requires schools that have historically underperformed and receive federal Title I funds to submit progress reports yearly. In addition, NCLB provides students who attend low-performing schools the choice of transferring to a different public school in their
district or a charter school if their public school fails to meet district or federal educational mandates.

Although the main objective of NCLB is to improve educational quality through test-based accountability and to provide students flexibility in terms of educational choice, it has presented more problems than solutions. For example, NCLB does not address the issue of institutional inequality that contributes to student underperformance. Moreover, as a result of the pressure to improve student test scores, curricula have become centered around enhancing test-taking skills instead of learning acquisition. Another problem with a system of accountability based on test score performance is that questions asked on standardized tests are racially and culturally biased. This places an already vulnerable student population at risk of underperforming, because the educational experiences of black and Hispanic students vastly differ from those of white and Asian students from more affluent schools (Steele 1992; Horn 2005). Standardized tests are good measures of the skills obtained from schooling, so if lower-SES students are less likely to receive adequate levels of instruction compared to their more privileged peers, it should come as no surprise that the majority of low-SES students have trouble meeting federal, state, and district expectations.

Achievement on standardized tests is used to determine advancement to the next grade, high school graduation, and admission to college. In most states, students attending public schools are required to take high school exit exams in order to receive their diplomas. For example, the California High School Exit Examination, enacted as state law in 2006, was designed to ensure that all high school graduates have received an adequate foundation in English-language arts and mathematics, based on state standards. According to the California Department of Education (2006), by the end of eleventh grade white students had the highest pass rate on the English-language arts portion of the exam at 96 percent, and Hispanic and black students had the lowest at 83 percent. Also, by the end of eleventh grade Asian students had the highest passing rate in mathematics at 97 percent and African American students had the lowest at 76 percent. Test outcomes from this diverse state suggest that exit exams can increase the drop-out rate and limit degree attainment for minority students. Results also provide an indication of how marginalized students will perform nationally once other states implement exit exams as a main criteria for graduation.

Preparation for high school exit exams and earned grades are directly associated with performance on the Scholastic Aptitude Test (SAT) used for postsecondary admission. National mean SAT scores disaggregated by race and ethnicity show disparities in verbal and math scores. Most recent data from 2002 show that white and Asian students had the top scores at 1060 and 1070, respectively, whereas Hispanics averaged 903 and blacks were at the bottom at 857 (College Board 2002). Racial and ethnic variation in grades parallels that of test scores. Most recent national data reporting mean grade-point averages (GPA) for high school twelfth graders indicates that blacks are the lowest at 2.63 compared to 2.80 for Hispanics, 3.01 for whites, and 3.20 for Asian/Pacific Islanders (U.S. Department of Education 2000). Many contend the underrepresentation of minorities in colleges and universities is a direct result of low GPA and SAT scores, poor preparation for college-level work, and limited access to postsecondary education.

The differing school environments that condition disparities in educational attainment for minorities have implications for the persistence of inequality that has consequential and enduring effects on higher education and labor market participation. Individuals with higher education degrees are more likely to have better paying positions, job security, and wealth compared to individuals with low levels of schooling (Mare 1995). Table 3 shows the percent distribution of white, black, and Hispanic students between the ages of eighteen and twenty-four who completed high school between 1993 and 2004. As can be seen, the distribution of high school diplomas varies: Whites had the highest graduation rate at 82 percent, Hispanics had substantially the lowest at 71
percent, and blacks were in between at 81 percent. Although the data is not disaggregated by geographic region, gross disparities in high school degree attainment are apparent. To show the negative effects of differentials in high school completion for postsecondary education, Table 4 illustrates the percent distribution by race of high school graduates between the ages of eighteen and twenty-four who enrolled in colleges and universities between 1993 and 2004. Comparing enrollment rates for 2004, for example, the table illustrates that 41 percent of whites, 31 percent of blacks, and 24 percent of Hispanics were enrolled at postsecondary institutions. What is most astonishing about these results is that the majority of blacks (69 percent) and Hispanics (76 percent) did not persist to college directly after high school. This finding is significant considering that blacks are 12.3 and Hispanics are 12.5 percent of the U.S. population, respectively (U.S. Census 2002).

For minority students who do pursue university degrees, their educational experiences, grades and graduation rates are much lower compared to white and Asian students. In fact, once in college minority students receive grades that are on average half a letter below those of their white classmates (Steele 1992). Racism, financial constraints, lack of preparation for college-level work, few opportunity programs on campus that would help facilitate the adjustment to rigorous academic work for minority students, and slower time to degree rates are among the factors that explain college outcomes for minority students. Research has shown that minority students experience additional constraints that can negatively affect academic achievement.

For example, in a study of college students attending selective colleges and universities, Camille Charles, Gniesha Dinwiddie, and Douglas Massey (2004) found that for high-achieving black and Hispanic students from residentially segregated neighborhoods, college-related, economic and family social stress negatively produced a drop in academic performance and levels of satisfaction with college. Although minority students work hard academically to attend and succeed in college, there are additional stressors and constraints that substantially and negatively impede their educational progression.

Failure to obtain a high school diploma or college degree has direct implications on earning potential for minority youth who go directly into the labor market. Table 5 illustrates mean yearly earnings of workers eighteen years and older between the years of 1993 and 2003,

differentiated by level of educational attainment. The data illustrate that in 1993 mean earnings for blacks and Hispanics were similar for individuals without a high school diploma. It is not until 2003 that blacks without a high school diploma have the lowest mean earnings per year, compared to Hispanics and whites without a diploma. If we look at earnings for individuals with high school diplomas in 1993, blacks and Hispanics have similar earnings; blacks and Hispanics, however, made roughly $3,000 less than whites with the same level of educational attainment. On the other side, for those with college degrees, whites made $5,000 more on average compared to minorities in 1993. Moreover, in 2003 disparities in mean earnings by level of educational attainment are more pervasive. Whites with bachelor degrees, on average, made $10,000 more than minorities with bachelor degrees. Although minorities on average earn less than whites with similar working experience and degree attainment, having a college degree substantially increases earning potential for everyone, particularly blacks and Hispanics.

CONCLUSION

The adverse effects of inequality have long-term implications for educational opportunities and earning potential, particularly for racial/ethnic minorities. Returning to the original question of whether education improves life chances or reinforces social inequality, from the evidence provided it is apparent that educational disadvantages experienced by racial/ethnic groups have snowball effects. Most importantly, laws such as NCLB, school voucher policies, the increase in the use of standardized testing as indicators of determinants for persistence, and various school accountability mechanisms are very limited in scope. For example, NCLB is not intended to produce equal segregated schools, but to fix a macro problem with micro methodologies. Moreover, the impact of residential segregation on primary, secondary, and postsecondary educational outcomes speaks volumes about the strong negative influence of systemic racism, which has effects that endure long after minority students have left the educational system.

As the demographics of the United States change, educational policy will need to take a more progressive approach to alleviating racial/ethnic disparities in educational outcomes. At the present time, the Hispanic population is growing and is fast becoming more segregated compared to blacks. Moreover, due to the failure of social policy in taking an active role in desegregating the public educational system, public schools are becoming “resegregated” (Orfield 1999), where gaps in achievement are once again widening, and classrooms are still overwhelmingly racially homogenous. Overall, the institutional inequalities that condition racial/ethnic variations in educational outcomes must first receive more attention if the federal government and policymakers are to deliver what they promise.

**EDUCATIONAL QUALITY**

Education often yields higher earnings, opens career opportunities, improves health, widens social circles, and increases political activity. Although education can play a central role in the economic development of a society, there is no consensus about measuring quality, nor even assurance that more effort will necessarily yield positive results.

Counts of inputs like teachers and classrooms or, more broadly, spending per student, have been used to challenge school segregation and unequal school financing. Measures of outputs, however, are necessary for judging effectiveness. More years of schooling is a simple measure of output that is effective as long as the skills developed have value. When time spent in school builds pointless skills, years of schooling is a poor measure of educational quality. Indeed, there comes a point at which further schooling is not worth its cost, and that point differs among students, reflects the character of the schooling, and depends on the opportunities for people with different kinds of schooling.

A better measure of output, then, is the gain in earnings over a lifetime due to education. Because each person can have only one level of education and lifetime earnings, estimating the gains from added education involves comparing averages for otherwise similar people with different levels of education well after graduation.

The average gain in earnings from a baseline level of education to a higher level can be summarized as a financial flow. Consider an amount in a mutual fund before the education begins (earning interest at market rates) that would pay out the gain in earnings due to better education each year over a lifetime with the balance in the fund dropping to zero when the person retires. The initial
amount needed in such a fund is called the *present value* of the gain in earnings from the added education. The student’s cost of the schooling is the present value of any tuition, transportation, and, for older students, earnings foregone to attend school. When the present value of the added earnings exceeds the present value of the cost of the schooling, the expenditure on education increases wealth. This is a benchmark for educational quality. The higher the present value net of cost, the higher the quality of education. Just as financial capital yields future payoffs, education creates human capital with its own future payoff.

Measuring quality as the gain in earnings often means that, compared to white males, women and underrepresented minorities have higher returns. Education can narrow the gap in earnings from wide differentials with low education to smaller gaps with more education. A larger gain often means a higher financial return for women and minorities than for white males.

Since 1980, the return to education has been high in the United States, about a 10 percent increase in earnings for each added year of schooling with the implication that the schooling is of good quality. The gains arose primarily because the earnings of workers with only a high school education or less have fallen remarkably.

Looking beyond gains in earnings, many students add the value of improved health, more effective participation in politics, and personal fulfillment as additional dimensions of benefit. In addition to developing skills, education identifies talents that allow a better match of individuals to opportunities. A better match may yield both higher earnings and more personal fulfillment. It is difficult to distinguish the degree to which measured gains in earnings from education reflect learning versus simply identifying talent.

Educational gains extend beyond the individual student. Less-educated workers are more productive when working with more-educated workers. For this reason, each of us is affected by the educational achievement of other people’s children. Voters and taxpayers, even those without children, often support expenditures on education to promote the general welfare.

Education may, however, be wasteful when the goal is only to gain relative position. When a second-rank student applies more effort to top the first, the first responds with more effort to retain place. The result can be that every student down the hierarchy gets more education to gain place, but when all do so, the rank order and pattern of earnings are unchanged. An educational system that promotes hierarchy to the exclusion of other goals will be enervating for all.

Measuring quality as the financial value of education involves using information from many people observed years after the completion of their education. Such measures are of limited value in judging the details of educational services. Analysts turn to tests to measure educational performance that is specific to school and class size, teacher characteristics, peer students in the classroom, and attendance. Each affects test scores. The increase in test score this year over last year measures a student’s gain in knowledge during a school year. The difference in test score is a measure of the value added during the school year, an indicator of educational quality. The analysis, however, must account statistically for other influences like native talent and family background to isolate the effect of the school. Because some attributes of schools are not subject to management’s control, an analyst may seek to isolate features of the school that the school can control from those it cannot. For example, a school may have little influence on student turnover as families migrate.

Moreover, test scores are limited measures of educational quality. Standardized tests ask the same questions (or questions calibrated to have the same expected pattern of results) each time they are given. Many such tests have a limited scope, often aimed at judging the performance of average students. Some tests do a poor job of measuring gains among students who learned this year’s material the previous year. They also do a poor job of measuring gains among students who are far below average. Test scores support insightful analysis of educational quality in carefully devised statistical studies, but they are not foolproof.

Standardized tests are particularly problematic when used as the basis of incentive systems for schools. Such systems rarely attempt to control for sources of differences in test scores that are beyond the control of the school. Schools may systematically game the tests. Drilling students on the specific items on the test may cause test scores to rise as learning falls. Rewarding schools on the basis of average test scores will focus a school’s attention on the middle students, with less attention given to others. A focus on tests also diminishes educational outcomes that are not monitored by tests.

Standardized tests play a pivotal role in efforts to privatize the provision of elementary and secondary education. Private operators might have sharper incentives to provide more quality for a given expenditure per student through contracts, charters, or by scholarship and vouchers. The performance of independent operators receiving public funds may be judged unevenly, however, when other factors that influence test scores are not taken into account. Whether private operators yield consistently better performance when other attributes of students are accounted for remains controversial.

Clever teachers and effective principals turn their students’ curiosity into discovery. Quality schools engage students, promote community, develop abstract thinking.
skills, and raise aspirations. Students develop talents they did not know they had and acquire valued skills. Physical, social, and visual skills grow with mathematical, language, and problem-solving skills. Quality schools are grounded in the lives of their students and challenge them on many levels. Social science can inform judgments about quality but cannot provide formulae that substitute for insightful leadership.

EFFICIENT MARKET HYPOTHESIS

The efficient market hypothesis (EMH) holds that financial markets make efficient use of available information so that traders cannot base profitable trading strategies on available information. Such information will already be incorporated in asset prices, because when traders take advantage of profitable arbitrage opportunities, their trading changes the prices of assets, and thus public information cannot be used to outperform the market. The weak form of EMH holds that all past prices of an asset are fully reflected in its current market prices, so that charting and technical analysis of stock price movements cannot provide an abnormal profit. The semistrong form of EMH views asset prices as incorporating all publicly available information, so that fundamental analysis of a company’s business prospects, based on its reports and on published news and analysis, will not yield an excess return. According to the strong form of EMH, prices of securities fully reflect all public and private information, so that even insider trading does not achieve excess profits (see Fama 1970).

Although some earlier observers had the concept of market efficiency due to arbitrage (at least in the weak form of EMH and arguably in the semistrong form), notably Jules Regnault (d. 1866) (see Franck Jovanovic in Poitras 2006–2007, vol. 1), the mathematical implications were first set out with regard to the prices of options on French government bonds by the probability theorist Louis Bachelier (1870–1946) in his 1900 dissertation *Théorie de la spéculation* (translated in Cootner 1964). By analogy to fair bets in games of chance, Bachelier showed that the absence of unexploited arbitrage opportunities implies that changes in asset prices are unpredictable, so that in efficient markets asset prices follow a random walk (in discrete time) or Brownian motion (in continuous time), stochastic processes that Bachelier characterized five years before Albert Einstein (1879–1955) independently formalized Brownian motion for gas particles.

Although Bachelier’s thesis was published sixty years before John Muth proposed the rational expectations hypothesis, Bachelier assumed that speculators had what Muth would call rational expectations: Their expectations of prices were correct except for completely unpredictable, random errors. Disillusioned with the failure of stock market forecasting services to predict the crash of 1929, Alfred Cowles III (1891–1984) compiled evidence (1933) that the forecasters did no better than random portfolios would have done, so that the fees paid by their subscribers were wasted—although Cowles (1944) later changed his mind, accepting that one unnamed forecaster (apparently William Peter Hamilton’s [1867–1929] version of the Dow theory) had outperformed the market more often than could be attributed to chance. Cowles questioned why anyone who could actually predict the movement of stock prices would sell the prediction for a fee instead of making a fortune by trading on his or her own account. In 1934 Holbrook Working (1895–1985) showed that, for there to be no unexploited possibilities for profitable arbitrage, commodity prices must follow a random walk.
tle influence until the late 1950s (see Cootner 1964; Fama 1970; Poitras 2006–2007, vol. 2).

In 1958 Franco Modigliani (1918–2003) and Merton Miller (1923–2000) used the no-arbitrage principle to argue that firms cannot increase their market value by altering how their financial structure is divided between debt and equity, because if a firm could do so, then individual investors could make arbitrage profits by analogous portfolio changes between shares and bonds (see Miller et al. 1988). The Modigliani-Miller proposition abstracted from any differences in tax treatment of different financial structures and from the asymmetry that corporations have limited liability but individual investors do not.

As influentially expounded by Eugene Fama (1970) and Burton Malkiel ([1973] 1999), the weak form of EMH implies that the only way to profit from charting and technical analysis of stock price movements is by selling worthless forecasts to the gullible, and the semistrong form implies that investors should just invest in broad market averages, avoiding the costs of active portfolio management and security analysis. These ideas were anathema to the forecasters and managers whose livelihood they threatened, to successful investors who were told their above-average risk-adjusted returns were due to luck rather than skill, and to the widely held hope that there is some expert or formula that, for a thousand dollars, will tell one how to make a million. Nonetheless, the weak and semistrong forms of EMH became increasingly accepted and contributed to the growth of index funds.

The strong form of EMH, implying the failure of laws against insider trading, was advanced more tentatively even by firm believers in the weak and semistrong forms. However, the current status of the efficient market hypothesis is unsettled (see the debate between Malkiel and Shiller 2003). Financial markets cannot be more than approximately efficient, because perfect information efficiency would leave no incentive for professionals to discover the information that is incorporated in prices. Andrew Lo and Craig MacKinlay (1999) find evidence of serial correlation in stock price movements, contrary to the weak form of EMH. Robert Shiller (1989, 2005) presents evidence of excess volatility of asset prices, which move not just because of random shocks and rational expectations of underlying fundamentals but also because of what John Maynard Keynes (1883–1946) called "animal spirits" and Alan Greenspan termed "irrational exuberance," as during the Internet bubble of the late 1990s. Defending the EMH against advocates of behavioral finance, Burton Malkiel argues that speculative bubbles can be identified only in retrospect and that "whatever patterns or irrationalities in the pricing of individual stocks that have been discovered in a search of historical experience are unlikely to persist and will not provide investors with a method to obtain extraordinary returns. If any $100 bills are lying around the stock exchanges of the world, they will not be there for long" (Malkiel and Shiller 2003, p. 80).

EGALITARIANISM

Egalitarianism is a political ideology centered on the belief in human equality. As a basic concept, equality by itself refers only to a relation, such as “less than” or “greater than,” rather than a quality or essence. To judge two things equal, we must also specify the relevant qualities they have in common. Therefore, egalitarianism is the belief that all humans share an essence or quality that makes them equal. Although all egalitarians believe in equality, they often differ in their understanding of the qualities all humans share.

Every form of egalitarianism is cosmopolitan and inclusive. Those who see only the members of their own group as equal are not egalitarian. Because egalitarianism is always based on a theory of universal human commonality and because such universal human qualities are difficult to define, their essence is often unspecified by egalitarian thinkers. Nonetheless, anyone who believes all humans are equal must also believe all humans have some kind of essence or quality in common, because without commonality there can be no equality.

All theories of universal human commonality fall into one of two categories. Either the essentially human qualities come from the laws of nature, or those qualities are transcendent or spiritual. Theories of a universal human nature belong to the first category, whereas the belief in a transcendent spark of essential human dignity belongs to the second. In European and North American thought, the egalitarianism of nature is descended from ancient Greek ideas about the invariable, underlying patterns that govern all things. These patterns are understood as scientific laws, and human nature in this view is universal and relatively invariable. Transcendent or supernatural ideas of human equality developed from the traditions of monotheism, according to which a supernatural creator gave to all humans a spark of the divine essence. According to this view, all humans share the power of self-creativity, the ability to define their own nature.

Hence these two kinds of egalitarianism are at odds with each other on the question of human malleability. In the egalitarianism of human nature, the natural qualities shared by everyone vary only within a limited range, whereas in the egalitarianism of self-creativity, all humans share the power to define their own essence. Therefore the egalitarianism of nature tends to be more conservative, and the egalitarianism of self-creativity is usually more liberal or progressive.

Although the egalitarianism of human nature is seen as too limited by those in the tradition of self-creativity, historically it led to ideas of natural rights that inspired revolutions. The U.S. Declaration of Independence begins by asserting the natural rights of life, liberty, and the pursuit of happiness, which in turn were based on John Locke’s ideas of human nature. In this view, the forces of nature provide humans with fixed wants and the power of labor to fulfill them. Equality is the common freedom to pursue our given wants with our natural powers. All humans have the same nature and therefore the same rights.

In the nineteenth century the egalitarianism of human nature increasingly came to be seen as inauthentic by those who saw freedom as the ability to transcend such limits. The equality of natural powers led to inequalities of social outcomes, which economic theories of human nature seemed to excuse. In the alternative view, to achieve true equality we must first eliminate the inherited constraints of the past. According to the newer egalitarianism of self-creativity, the Lockean theory of human nature is a mere social construct used by the rich to justify their privileges. True equality instead requires the ability to make society anew. For egalitarians such as Karl Marx, labor is not just a natural force but also, more importantly, the power of human self-existence, which the rich had alienated from the poor in a way that robbed them of their essential humanity. Only when the workers of the world were reunited in the self-creative circle of production and consumption would true equality be achieved.

In the early twenty-first century the two dominant versions of egalitarianism continue to compete in the politics of Western societies. Almost everyone is an egalitarian of some sort, but equality continues to be understood in different ways. In the egalitarianism of human nature, governments should provide fairness of competition and opportunity, but success depends on natural talent and effort. In the egalitarianism of self-creativity, politics is itself a mode of social self-definition, and equal participation in self-government is both a means and an end of equality. The politics of all democracies contain some mixture of these competing beliefs.

**Eigen-Values and Eigen-Vectors, Perron-Frobenius Theorem: Economic Applications**

Production prices, proportionate growth, maximum rate of profit and growth, and Italian economist Piero Sraffa’s standard commodity can be easily presented and analyzed by referring to the Perron-Frobenius theorem, which needs mathematical definitions concerning eigen-values and eigen-vectors.

**Eigen-Values, Eigen-Vectors of a Square Matrix**

Given a square matrix $A$ composed of real numbers $\alpha$, consider the vector $x$ such that $Ax = \alpha x$. Obviously the vector $x = 0$ satisfies the equality $Ax = \alpha x$ for any real number $\alpha$. The aim is to determine the non-zero vectors $x$ and the real numbers $\alpha$ such that $Ax = \alpha x$.

Consider a square matrix of order $k$. If there exists a real number $\alpha$ and a non-zero vector $x$ such that $Ax = \alpha x$, $\alpha$ is said to be an eigen-value of $A$ and $x$ is an eigen-vector corresponding to $\alpha$.

**Determination of the Eigen-Values of $A$**

Any eigen-value $\alpha$ of $A$ is such that there exists a non-zero vector $x$ which satisfies $Ax = \alpha x$, where $I$ is the identity matrix of the same order as the square matrix $A$. Thus any eigen-value $\alpha$ of $A$ satisfies $(A - \alpha I)x = 0$. Since $A - \alpha I$ is a non-zero matrix and since $x$ is a non-zero vector, we must have $|A - \alpha I| = 0$, (recalling that $|A - \alpha I|$ is the determinant of the square matrix $[A - \alpha I]$), i.e., $\alpha$ is a solution of the equation of the $k^{th}$ degree $|A - \alpha I| = 0$, since the square matrix $[A - \alpha I]$ is of order $k$.

The equation $|A - \alpha I| = 0$ is called the characteristic equation of matrix $A$ and has at most $k$ real solutions. If the characteristic equation has no real solution, matrix $A$ has neither real eigen-values nor eigen-vectors with real components.

**Determination of the Eigen Vectors of $A$**

If the real number $\bar{\alpha}$ is a solution of the characteristic equation $|A - \alpha I| = 0$ of the square matrix $A$, $\bar{\alpha}$ is an eigen-value of $A$. Any non-zero eigen-vector $x$ of $A$ associated with $\bar{\alpha}$ satisfies the matrix equation $Ax = \bar{\alpha}x$ or $(A - \bar{\alpha}I)x = 0$. This equation represents in fact a system of $k$ homogeneous linear equations with $k$ unknowns, i.e., the components $x_1, x_2, ..., x_k$ of the eigen-vector $x$. Since $|A - \bar{\alpha}I| = 0$, the rank of matrix $A - \bar{\alpha}I$ is at most equal to $k - 1$. One can then distinguish the following cases:

- Rank $(A - \bar{\alpha}I) = k - 1$: one of the components, say $x_i$, can be arbitrarily chosen and the $k - 1$ others are uniquely determined by the value chosen for $x_i$. The eigen-vector $x$ is thus uniquely determined up to the multiplication by scalars.
- Rank $(A - \bar{\alpha}I) \leq k - 2$: $p$ components ($p \geq 2$), say $x_{i_1}, x_{i_2}, ..., x_{i_p}$, can be arbitrarily chosen and the $k - p$ others are determined by $x_{i_1}, x_{i_2}, ..., x_{i_p}$. One can then have $p$ linearly independent eigen-vectors corresponding to the same eigen-value $\bar{\alpha}$.

Only one eigen-vector $x$ (up to the multiplication by scalars) corresponds to the real eigen-value $\bar{\alpha}$ when $\bar{\alpha}$ is a simple root of the characteristic equation. But when the eigen-value $\bar{\alpha}$ is a multiple root of order $p$ of the characteristic equation, then:

- either one eigen-vector $x$ (up to the multiplication by scalars) is associated with $\bar{\alpha}$; in this case $\bar{\alpha}$ is said to be a semi-simple eigen-value;
- or several linearly independent eigen-vectors correspond to $\bar{\alpha}$.
One can also determine a vector \( y \) such that \( yA = \alpha y \).

Call \( y \) the eigen-vector on the left of \( A \) associated with the eigen-value \( \alpha \). The vector \( x \) such that \( Ax = \alpha x \) is then the eigen-vector on the right of \( A \) associated with \( \alpha \).

One can determine the eigen-values and the eigenvectors of the matrix:

\[
A = \begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9
\end{bmatrix}.
\]

The eigen-values \( \alpha \) of matrix \( A \) are the solutions of a third degree equation \( |A - \alpha I| = 0 \) which can be written

\[-\alpha^3 + (43/36)\alpha^2 - (5/6)\alpha + (35/1296) = 0.\]

Thus \( A \) has three eigen-values \( \%, 7/36 \) and \( \% \), which are the simple roots of the characteristic equation.

One can determine an eigen-vector on the right \( p \) and an eigen-vector on left \( q \) of matrix \( A \) associated with the highest eigen-value \( \alpha \).

An eigen-value on the right \( p = \begin{bmatrix} p_1 \\ p_2 \\ p_3 \end{bmatrix} \) of \( A \) associated with the eigen-value \( \alpha = \% \) satisfies the matrix equation \( (A - \%I)p = 0 \), and its components \( p_1, p_2, \) and \( p_3 \) are solutions of a system of homogeneous equations which is an undetermined system of rank 2. If one gives to \( p_1 \), the value 11, one has \( p_2 = 10 \) and \( p_3 = 8 \); i.e., \( p = \begin{bmatrix} 11 \\ 10 \\ 8 \end{bmatrix} \) is an eigen-vector on the right of \( A \) associated with \( \alpha = \% \) and any vector

\[
\begin{bmatrix} \mu \\ 10\mu \\ 8\mu \end{bmatrix}
\]

where \( \mu \) is any scalar, is also an eigen-vector on the right associated with \( \alpha = \% \).

Similarly, an eigen-vector on the left \( q = (q_1, q_2, q_3) \) of \( A \) associated with the same \( \alpha = \% \) satisfies the matrix equation \( q(A - \%I) = 0 \) and its components \( q_1, q_2, \) and \( q_3 \) are solutions of a system of homogeneous equations which is an undetermined system of rank 2. If one assumes \( q_1 = 1 \), we have \( q_2 = \% \) and \( q_3 = \%, \) so \( q = (1, \%, \%) \) is an eigen-vector on the left of \( A \) associated with \( \alpha = \% \) and any vector \( q = (\mu, \%, \%) \), where \( \mu \) is any scalar, is also an eigen-vector on the right associated with \( \alpha = \% \).

**Indecomposable Matrix** A square matrix is said to be **decomposable** or reducible if there exists a permutation \( \tilde{A} \) of \( A: \tilde{A} = \begin{bmatrix} A_1^1 & 0 \\ A_2^1 & A_3^1 \end{bmatrix} \) where \( A_1^1 \) and \( A_3^1 \) are square matrices.

\( \tilde{A} \) is said to be a **quasi-triangular** matrix, i.e., containing only zeros at the intersection of the first rows and its last columns.

When a square matrix is not decomposable, it is said to be **indecomposable** or **irreducible**.

**Matrices with Nonnegative Elements** A square matrix \( A \) is said to be **nonnegative** when \( a_{ij} \geq 0 \) for any \( i \) and any \( j \).

\( A \) is said to be **semi-positive** when \( a_{ij} \geq 0 \) for any \( i \) and any \( j \) and \( A \neq 0 \).

\( A \) is said to be **positive** when \( a_{ij} > 0 \) for any \( i \) and any \( j \).

**Perron-Frobenius Theorem** Any indecomposable semi-positive square matrix \( A \) possesses a positive eigen-value \( \alpha A \) and a positive eigen-vector \( x \) corresponding to \( \alpha(A) \). The positive number \( \alpha(A) \) is a simple root of the characteristic equation \( |A - \alpha I| = 0 \) and is the only eigen-value of matrix \( A \) with a positive eigen-vector. The absolute values of the \( k - 1 \) other eigen-values of matrix \( A \) are not greater than \( \alpha(A) \).

The positive eigen-value \( \alpha(A) \) (or equivalently \( \alpha^* \)) of the indecomposable non-negative square matrix with an associated eigen-vector \( x > 0 \) is called the dominant eigen-value of matrix \( A \).

**PERRON-FROBENIUS THEOREM AND ITS ECONOMIC APPLICATIONS**

**Profit Rate and Production Prices with “Advanced Wage” Assumption** Consider a square input-output system with quite standard assumptions except one: one shall assume that “wages are consisting of the necessary subsistence of the workers and thus entering the system on the same footing as the fuel for the engines or the feed for the cattle” (such is the assumption made by Sraffa in *Production of Commodities by Means of Commodities* [1960, p. 9]). In such a simplified case, which corresponds to classical economists’ and the German political philosopher Karl Marx’s assumption of “advanced wage,” one can interpret the preceding matrix equation \( Ap = \alpha p \) in the following way. When \( \alpha < 1 \) (which appears in all productive systems generally considered), one can write \( \alpha = 1/(1 + R) \) with \( R > 0 \) and one gets: \( p = (1 + R)Ap \).
appears, with uniform positive profit rate $R$, a vector positive system $p$; each element of vector $p$, say $p_i$, represents the “cost of production” of each commodity, since it takes into account not only materials used in the production of the commodity considered but also wages paid to workers. However, since we consider here an indecomposable production it is better to resort to the denomination of “production prices” and not “costs.”

In matrix notation:

$$A p (1 + R) = p \iff A p = \frac{1}{1 + R} \cdot p = \alpha \cdot p$$

which means that $p$ is the eigen-vector corresponding to the eigen-value $1/(1 + R)$. In this way, one determines simultaneously the dominant eigen-value $\alpha$ of $A$ (i.e., the rate of profit $R$) and the corresponding eigen-vector $p$ (i.e., the $[k - 1]$ relative prices) are necessarily positive from the Perron-Frobenius theorem.

Note that in the preceding example, one gets $\alpha = \%$ and consequently $R = 20\%$ with $p = \begin{bmatrix} 11 \mu \\ 10 \mu \\ 8 \mu \end{bmatrix}$ which means that one determines in such a case the uniform rate of profit and the whole structure of prices, or exchange rates. One must note that this allows determination of price structure, not exact level, since $\mu$ is any scalar. (Money quantitative theory may be used to find price level but this is quite another problem and there exist many other possibilities.)

**Profit Rate, Production Prices with Wages Paid “Post Factum”** Whereas classics assumed wages to be advanced by the capitalist, another assumption is that wages are paid as a share of the annual product, *post factum* according to Sraffa’s terminology. In such a case, quantities of commodities necessary for workers’ subsistence no longer appear in the technology matrix. The quantity of labor employed in each industry (with labor of uniform quality) must now be entered explicitly. In such a case, and getting back to the preceding example, the production price system must now be written $(1 + \eta)A p + w L = p$, with $w$ as a scalar for wages paid to workers and $L$ a column vector representing labor needs for production of each commodity. In the particular limit case of $w = 0$, one comes back to the preceding case so $R = \frac{1 - \alpha}{\alpha}$ represents the “maximum rate of profit” determined by the dominant eigen-value of matrix $A$.

**Price-Movements and Sraffa’s “Standard Commodity”** Consider the preceding system $(1 + \eta)A p + w L = p$. Obviously, prices cannot stay unchanged when distribution varies. But, the study of the price-movements that accompany a change in distribution is complicated by the necessity of having to express the price of one commodity in terms of another that is arbitrarily chosen as standard. For instance, when one studies the variations of price $p_i$ when distribution changes, and one has already chosen (implicitly or explicitly) a peculiar commodity price $p_j$ for “numeraire” or “standard,” it is impossible to determine if the change in $p_i/p_j$ arises from the variation of the commodity which is measured or from those of the measuring standard.

This problem of an “invariable standard” has already been considered by the English economist David Ricardo who imagined, in a rather abrupt way and without any justification, that “gold” could be such an invariable standard. The presentation of the modern solution, given by Sraffa, can be given using preceding developments concerning eigen-vectors and eigen-values.

Remember that a particular commodity ($i$) is produced by using a row vector of intermediate consumption $a_i$ and a quantity $l_i$ of labor. Its price is given, with preceding notations, by equation $p_i = (1 + \eta)a_i + l_i$. When distribution changes, $p_i$ will change because of modifications of the value of the different “layers” composing the means of production of the commodity considered; such heterogeneity implies that if we consider the ratio of the value of such a commodity to its means of production, this ratio cannot remain unchanged when distribution changes; this is obvious since $p_i/a_i = 1 + r + \frac{wL}{a_i}$.

So, such ratio cannot, in general, be invariant to changes in distribution. But does there exist a particular commodity, or a “basket” of commodities, a “composite commodity” $u = (u_1, u_2, \ldots, u_j)$ satisfying this condition? If such is the case, the condition should be written $\frac{u p}{u A p} = Cte$, where $u p$ is the price, or value, of the “composite commodity” and $u A p$ price, or value, of means of production $u A$. And one knows from preceding developments that in the case of semi-positive indecomposable matrix $A$ there exists a unique positive vector $q$ which satisfies this condition since $qA = \alpha q$ with $\alpha = 1/(1 + R)$.

In the preceding example, the “composite commodity” is vector $q = (\mu, \% \mu, \% \mu)$ where $\mu$ is any scalar.

Such “balanced” commodity would have the same proportions in all its layers. As noted by Sraffa, “It is true that, as wages fall, such a commodity would be no less susceptible than any other to rise or fall in price relative to other individual commodities; but we should know for certain that any such fluctuation would originate exclusively in the peculiarities of production of the commodity which was being compared with it, and not in its own.” Such commodity is the standard capable of isolating the
PROPORTIONAL GROWTH: DUALITY

Consider a square indecomposable semi-positive matrix, as for instance the preceding example. In such a case, where the dominant eigen-value is \( \alpha = \frac{5}{6} \), one can get:

- uniform rate of profit \( R = 20\% = \frac{1 - \alpha}{\alpha} \) and prices of production structure \( p \) determined by right eigen-vector: \( p = (1 + R)Ap \)
- uniform growth rate \( R = 20\% = \frac{1 - \alpha}{\alpha} \) and levels of activities structure \( q \) determined by left eigen-vector: \( q = (1 + G)qA \).

Both uniform growth rate and uniform profit rate are determined by maximum matrix eigen-value. Of course, there is no final consumption, since constituents of matrix \( A \) take into account labor subsistence needs and all profits are re-invested. Note that, in such case of “proportional growth,” Marx’s analysis concerning rate of profit is validated: rate of profit \( R \) is equal to the ratio of total surplus-value to the value of total advanced capital.

Such model of “proportionate growth” implies some similarity with Hungarian-born mathematician John von Neumann’s model. However, the von Neumann model is much more complicated. Among the main differences:

- In the von Neumann model, there is a difference between free goods and economic goods, when in the preceding simplified model all goods considered are economic goods; free goods (such as industrial wastes, superabundant commodities) are explicitly taken into account in the von Neumann model.
- In the von Neumann model, all production processes (activities) are not necessarily used (there occurs a problem of “choice of techniques”) when here all processes are used (input-output matrix is square but rectangular in von Neumann).
- In the von Neumann approach there occurs a possibility of joint production: the “cattle breeding” process produces simultaneously meat and wool. Traditional input-output systems are single production processes: one process produces meat, another wool.
- In the von Neumann approach, the uniform growth rate and profit rate are no longer determined by referring to the Perron-Frobenius theorem.

EISENHOWER, DWIGHT D.

1890–1969

Dwight David “Ike” Eisenhower, a five-star general and the thirty-fourth president of the United States, was born in Texas and raised in Abilene, Kansas. He entered the United States Military Academy as a member of the class of 1915, later known as “The Class the Stars Fell On” for the record number of general officers it produced. As a West Point cadet, he was best known for his football skills and disregard for military discipline.
His first assignment was at Fort Sam Houston, Texas, where he met and married Mamie Doud. When the United States entered World War I (1914–1918), Eisenhower expected orders to Europe; instead, he commanded a training base near Gettysburg, Pennsylvania. Certain his lack of combat duty meant the end of his career, his fears were compounded by the rejection of his proposals for the role of tanks in future warfare. Those concerns diminished under the mentorship of Brigadier General Fox Conner, who arranged to have Eisenhower assigned to his staff in Panama. He encouraged and inspired Eisenhower, and ensured his selection to attend the Army’s staff college, where Eisenhower graduated first in his class. In the 1930s Eisenhower held key political-military posts under Army Chief of Staff Douglas MacArthur. He chafed at MacArthur’s control, and frequently requested reassignment. In 1939 MacArthur finally released Eisenhower for duty with troops.

Two weeks after the Japanese attack on Pearl Harbor, Army Chief of Staff General George Marshall summoned Eisenhower to serve as an Army war planner. Six months later, Eisenhower was selected to command all Allied forces in Europe. At the war’s end, Eisenhower was a five-star general, chief of staff of the Army, and an international hero touted as a possible Democratic candidate for president. In 1949 Eisenhower was named president of Columbia University. Despite his lack of academic credentials, he initiated important curriculum changes and established new academic programs. Eisenhower was recalled to active duty in 1950 to serve as Supreme Allied Commander–Europe.

Eisenhower was again urged to run for president in 1952, this time as a Republican challenging isolationist Senator Robert Taft for the GOP nomination. Taft was a strong candidate, but a compromise between those urging fiscal restraint and those promoting internationalist foreign policy resulted in Eisenhower’s nomination. The Korean War stalemate, and Eisenhower’s campaign promise to “go to Korea,” contributed significantly to his victory over Democrat Adlai Stevenson.

The cold war was President Eisenhower’s dominant foreign policy challenge. His efforts built a cohesive Allied defense capability in Europe, and his 1954 refusal to commit U.S. troops to support the French in Indochina is still considered one of his wisest decisions. His handling of the Hungarian uprising in 1956 and his use of the Central Intelligence Agency in covert operations were among his less successful policies. Eisenhower’s domestic successes included the interstate highway system. Following the Soviet launch of Sputnik, Eisenhower refocused the space program and increased support for math and science education. He used federal troops in Little Rock, Arkansas, to enforce court-ordered school desegregation. Eisenhower would not, however, support a broader, proactive civil rights agenda.

Eisenhower was reelected in 1956 despite concerns about a heart attack suffered a year earlier. His second term was marked by foreign policy disappointments in Cuba, heightened Soviet–U.S. tensions, and charges of corruption against his chief of staff. In his final address as president, he warned against the influence “sought or unsought” by the “military-industrial complex”—an imperative of the cold war with “grave implications.” Eisenhower died in 1969 and is buried in Abilene, Kansas, near the small home where he was raised.

ELASTICITY

In economics, elasticity measures a response of one variable to changes in the other variable. The concept of elasticity can be applied to any two variables, but the most commonly used are price elasticity of demand and elasticity of substitution between factors of production, consumer goods, or bundles of consumption in different periods of time (elasticity of intertemporal substitution).

Elasticity measures the percentage change in variable $Y$ in response to a 1 percent change in variable $X$. Formally, the elasticity of $Y$ with respect to $X$ is defined as
Elasticity of Substitution

\[ E_{Y,X} = \frac{\text{percentage change in } Y}{\text{percentage change in } X} \]

or, for continuous changes,

\[ E_{Y,X} = \frac{dY}{dX} \cdot \frac{X}{Y} = \frac{d \ln Y}{d \ln X} \]

The concept of the price elasticity of demand, which was introduced in 1890 by Alfred Marshall, measures the percentage change in the quantity of a good demanded when the price of this good changes by 1 percent. The demand is elastic if price changes lead to large changes in quantity demanded. The demand is inelastic if the quantity demanded does not respond much to changes in price. If demand is perfectly elastic, even a small increase in price will send the quantity demanded to zero. If demand is perfectly inelastic, the quantity demanded will be constant regardless of the price.

Price elasticity of demand for goods depends on the characteristics of the goods—that is, whether or not they are necessities and whether or not there are close substitutes for these goods. Price elasticity of demand also varies with the time horizon in consideration. For example, demand for gasoline is very inelastic in the short run, because people have to fill up their gas tanks, but in the long run, if prices remain high, people will switch to more gasoline-efficient cars and will demand less gasoline. By the estimates of the Mackinac Center for Public Policy, a 10 percent increase in the price of gasoline will lower the demand for it by 2 percent in the short run (elasticity of –0.2), and by 7 percent in the long run (elasticity of –0.7).

Price elasticity of demand also depends on how narrowly a good is defined. For example, demand for milk in general is quite inelastic, because there are no close substitutes. However, demand for milk of a specific brand is very elastic because there are many close substitutes (i.e., other brands of milk).

The concept of the elasticity of substitution was introduced independently by John Hicks and Joan Robinson in 1932 and 1933, respectively. It is used to measure how easily factors of production can be substituted for one another. For example, how much will the ratio of capital input to labor input in production increase if the ratio of capital cost to labor cost falls by 1 percent? Samuel de Abreu Pessoa, Silvia Matos Pessoa, and Rafael Rob (2005) estimate this elasticity to be 0.7, on average.

The concept of the elasticity of substitution can also be applied to consumption of goods, to measure how relative consumption of two goods is affected by their relative price. Most frequently, the concept of the elasticity of substitution in consumption is used to construct the bas-
are sufficiently extensive to admit conflicting interests, everything else follows, even if effective participation is far from universal” (1991, p. 10). Yet, political scientists and policymakers must be mindful not to equate elections—even free and fair ones—with democracy. Terry Lynn Karl (1986) emphasizes that focusing solely on elections could lead one to overlook where real political power lies. If an external actor—for example, the military or a foreign power—promotes competitive elections only when the results advance that actor’s self-interest and rescinds them when they do not, then one could hardly call the polity in question a democracy. Likewise, elections alone are not likely to constrain the temptations of corruption and graft. Rather, elections must operate alongside other democratic institutions—独立的 media, developed parties, the rule of law, and an active civil society—if they are to yield the codes of conduct associated with representative democracy. Despite these caveats, however, even critics of minimalist definitions of democracy view free and fair elections as necessary, though not sufficient, for democracy.

Although scholars generally agree that elections are necessary democratic institutions, little consensus exists as to what the rules governing elections should look like. For example, majority rule may seem like a logical option because the winner under such a voting system is the candidate or party that enjoys the support of over half of the voters participating in the election. However, Kenneth Arrow (1951) demonstrates that, when three or more candidates or parties compete in an election, it is possible for none of the candidates to enjoy the support of a majority. Just as social choice theorists, like Arrow and Amartya Sen (1970), have considered the normative implications of specific voting rules, other scholars have considered the advantages and disadvantages of different electoral systems.

One of the most important decisions for a new democracy is the selection of the parliamentary electoral system: the rules governing how popular votes are translated into parliamentary seats. Perhaps the most important feature of a parliamentary electoral system is its district magnitude—the number of legislators representing each electoral district. District magnitude is a fundamental feature for differentiating among parliamentary electoral systems. Single-member district systems, like the system used to elect members of the U.S. House of Representatives, are systems where each legislator represents a different district. Since only one seat is allocated from each district, the system’s average district magnitude equals one. At the extreme opposing a single-member district system is a proportional representation system where all representatives are elected in a single, nationwide district on the basis of party lists. In these cases, the average district magnitude equals the number of seats in parliament. A system’s average district magnitude is important because it directly influences the degree to which the number of seats that a political party receives is proportional to its share of the popular vote. The higher the district magnitude and the larger the assembly size, the better the fit between the percentage of votes cast for a party and the percentage of seats allocated to it.

Not all proportional representation systems have district magnitudes equal to the number of seats in their parliament, however. Some electoral systems divide the country into several multimember districts—districts that elect two or more legislators—even varying the number of representatives per district. Theoretically, then, the number of possible electoral systems is infinite. Indeed, electoral systems vary in many ways besides their district magnitudes. For example, they differ with regard to the mathematical formula used to allocate district seats. Single-member district systems can distribute each seat on the basis of plurality rule (i.e., the candidate with the most votes wins), majority rule, or preference voting (i.e., allowing voters to rank candidates and then distributing the vote according to those rankings). Likewise, different mathematical formulas are used for allocating parliamentary seats in multimember districts. In addition, some electoral systems require political parties to win a minimum level of support (e.g., a percentage of the vote or a number of district elections) to gain representation in parliament.

Although electoral systems take many forms, the consequences of electoral systems are commonly discussed in terms of their levels of proportionality (Duverger 1954; Rae 1967; Taagepera and Shugart 1989; and Cox 1997). Systems that are more proportional allow smaller parties representing specific societal interests a better chance of representation. However, since more-proportional systems grant more parties seats in parliament, they decrease the likelihood that one party will enjoy a parliamentary majority. Thus, a common criticism leveled against proportional representation systems is that they are more likely to produce coalition governments. Accordingly, proportional representation systems can produce unstable governments, governments in which coalition partners blame one another for policy shortcomings to shirk public accountability, and even governments where the policy influence of small parties outstrips their popular support simply because they emerge as critical to coalition formation. Under proportional representation systems, then, the process of government formation—as opposed to the actual election—can be decisive in determining whether voter preferences are fulfilled or denied.

Less-proportional systems, meanwhile, limit party fragmentation. They undermine the incentives that elites have to form new parties, as well as the incentives that vot-
Elections

Elections have to support new parties. Under single-member district plurality, in particular, one party is more likely to win a majority of seats in parliament. As a result, these systems can prove more responsive to changes in public attitudes: Where candidates need just a plurality of the vote to win elections, a small shift in the distribution of votes can create a significant shift in the distribution of parliamentary seats. Yet majoritarian systems can also frustrate public accountability. In New Zealand, for example, popular dissatisfaction with the two major parties that dominated politics spurred notable third-party voting in the 1970s and 1980s. However, New Zealand’s single-member district plurality system also kept third parties out of parliament while overrepresenting the two major parties. As a result, growing distrust of the system fueled a reform movement that ultimately led to a change in the electoral system itself (Denemark 2001).

Electoral systems, then, influence the degree to which elections fulfill different visions of democracy (Powell 2000). Less-proportional systems limit party proliferation while underrepresenting smaller groups in society. While these systems may make it easier for voters to hold policymakers accountable, the range of policymakers is more constrained than under more-proportional systems. More-proportional systems, meanwhile, permit the representation of a broader cross section of the public. However, these systems can make it more difficult for voters to hold policymakers accountable, since policies result from a complex bargaining process among a larger number of political parties in parliament.

Implicit in much of this literature, then, are the consequences that electoral systems have on attitudes toward government and on voter behavior during elections. Of course, extensive research exists on how and why people vote, and much of this literature goes beyond institutional impediments or incentives. For example, Anthony Downs (1957) argues that voters assess the expected costs and benefits associated with different options and choose the one whose policies are likely to net them the greatest gain. Why do they vote at all? The probability of one vote determining an election’s outcome is so small that any expected benefit associated with voting will not outweigh the costs of collecting information, or even going to the polls. Numerous scholars have sought to resolve this paradox within the framework of rational choice (Riker and Ordeshook 1968, Aldrich 1993), while others have chosen to understand voter turnout using social-psychological explanations (Teixeira 1987, Franklin 1996). Of course, when one compares voter turnout across countries, institutional explanations (i.e., the rules of the game) once again prove significant (Jackman 1987, Blais and Carty 1990).

ELECTORAL COLLEGE

Election college is the popular name for the system used to elect the president and vice president of the United States. Voters in the United States choose among candidates for these offices in November every four years, but the votes they cast are actually for another office, that of elector. In most states the names of the candidates for elector are not even on the ballot. Those chosen as electors collectively constitute the electoral college, a body that never meets as a group. State delegations of electors meet in early December in their respective state capitols to cast their “electoral votes” for president and vice president. These votes are then counted in early January at a session of Congress. If a majority of the electoral votes for president (at least 270 of a total of 538) is cast for the same person, that person wins the presidency. Likewise, if a majority of the electoral votes for vice president is cast for the same person, that person wins that office.

If no person receives a majority of the electoral votes for president, the selection of the president is placed with the U.S. House of Representatives. If no person receives a majority of votes for vice president, selection for that office is placed with the U.S. Senate. When this “contingent election” procedure is used to select a president, every state delegation in the House has one vote, which may only be cast for one of the top three recipients of electoral votes for that office. The winner must receive the vote from a majority of the states. When the contingent procedure is used to select the vice president, each senator has one vote, and only the top two recipients of electoral votes for that office may be considered. The winner must receive a vote from a majority of the senators.

This framework for electing a president and a vice president is specified in Article II, section 1, of the U.S. Constitution, ratified in 1789. This provision awards each state a number of electors equal to the number of members the state has in Congress, with one elector assigned for each of the state’s representatives and senators. Representatives are allotted to the states based on population, with the caveat that every state must receive at least one. Larger states therefore have more electors than smaller states. Every state, however, is allotted the same number of senators, two, regardless of population. This allocation, along with the minimum of one representative for every state, results in smaller states receiving proportionately more electoral votes, per population, than larger states.

Two amendments to the Constitution have directly altered the electoral college system. The Twelfth Amendment, adopted in 1804, separated electoral voting for the president and the vice president. Prior to this amendment each elector had two votes to cast and the person receiving the highest number of votes, provided that number constituted a vote from a majority of the electors, won the presidency. The vice presidency went to the person receiving the second highest number of votes. In the election of 1800 this resulted in the presidential and vice presidential candidates of one party receiving the same number of votes from a majority of the electors, pushing the selection of the president into the House. The Twelfth Amendment was added to preclude this type of result. The other amendment altering the electoral college was the Twenty-Third, adopted in 1961, which allowed voters in the District of Columbia, which is not a state, to choose as many electors as the least populous state, currently three. These electoral votes are cast in Washington, D.C.

Article II, Section 1, leaves the method of choosing electors to the states themselves, through their respective legislatures. Since 1836 all states but one have let the voters make this choice; the exception, South Carolina, switched to popular elections in 1860. Another important change made by states has been the adoption, by all but two states, of the “unit rule” for allocating electors to the candidates. Candidates for elector are vetted by the political parties and pledged to vote for that party’s candidates. This unit rule is a winner-take-all provision under which all of a state’s electors are awarded to the slate of presidential and vice presidential candidates that received the most votes in that state in November. Congress has specified that the unit rule applies to electors for the District of Columbia as well. Maine and Nebraska award two electoral votes to the slate of candidates winning a statewide plurality of votes, and another electoral vote to the slates winning a plurality within each of their U.S. House districts.

Commentators have described the electoral college as everything from “a brilliant constitutional device” (Ross 2004, p. 9) to “an anti-democratic relic of the eighteenth century” (Edwards 2004, p. 158). Those who defend the electoral college typically assert that it is a fundamental part of the American federal system of government that needs to be maintained, and that it provides more diverse interests, especially those of smaller states, with a voice in the election of the president. Those who find the system
antidemocratic argue that the people, not the electors, should determine who is elected. The votes cast in November for president and vice president, which only determine how electoral votes are distributed among sets of candidates, do show which slate of candidates was preferred by the people. With rare exception, the people’s choice and the electors’ choice are the same. But when the popular vote is close, the unit rule and the fact that electors are not allocated based strictly on population make it possible for the winners of the two votes to be different.

This happened in the 2000 election, when George W. Bush finished second in the popular vote with 47.8 percent, but first in the electoral vote with 50.5 percent. He was labeled by many as the “wrong winner.” Presidents and vice presidents chosen under the contingent election procedure likewise need not be the public’s choice.

The American public has demonstrated numerous times, in surveys and polls, that they prefer their president and vice president to be their choices, not those of intermediaries. A variety of reforms have been proposed that would accomplish this (see Edwards 2004, pp. 153–157; Bennett 2006, pp. 49–58, 161–178; and Koza et al. 2006).

ELECTORAL SYSTEMS
An electoral system is a set of institutional formulas producing a collective choice through voting. The main elements of an electoral system are: assembly size or total number of seats; district magnitude or number of seats to be elected in a district; the electoral rule to allocate seats from votes; and the ballot permitting the voter different choices. Different rules and procedures have combined these elements in many ways to produce a variety of electoral systems in the real world.

In late medieval and early modern assembly elections in local communities with homogeneous electorates, relatively simple electoral systems prevailed. A typical system until the nineteenth century was composed of: (1) multi-member districts; (2) plurality or majority rule; and (3) an open ballot. Essentially, voters could vote for their preferred individual candidates, and those with the higher numbers of votes were elected. This type of electoral system can produce a consensual individual representation of the community, especially in contexts of high economic and ethnic homogeneity in which it is relatively easy to identify common interests and select collective goods. Such systems have survived at the local level in some countries, and they are still typically used in meetings and assemblies of modern housing condominiums, neighborhood associations, school and university boards, professional organizations, corporation boards, and students’ and workers’ unions.

However, in contexts of relatively complex and heterogeneous electorates, simple electoral rules create incentives for the coordination of candidacies and voting. Forming a list of candidates, a faction, or, in more modern terms, a party, may move voters to vote en bloc rather than for individuals weighed separately. In multimember districts using plurality rule, voting en bloc (or the general ticket) may produce a party sweep or overrepresentation by a single party. Once partisan candidacies and partisan voting emerged in a number of countries by the mid-nineteenth century, some political leaders, activists, and politically motivated scholars began to search for new electoral rules and procedures that could reduce single-party sweeps and exclusionary victories. The two main options were either retaining plurality or majority rule but in smaller single-member districts, or retaining multimember districts but using new proportional representation rules.

RULES AND PROCEDURES
In a small single-member district, a candidate that would have been defeated by a party sweep in a larger multimember district may be elected. Thus, this type of system tends to produce more varied representation than the old system with voting en bloc. Several majoritarian rules can be applied. With simple plurality, the winner is the candidate supported by only a relative majority, that is, by a higher number of voters than any other candidate but not requiring any particular number, proportion, or threshold of votes. In practice, this makes it possible for generally binding decisions presumably decided by “majority” to actually be won by only a minority of voters. Plurality rule has traditionally been used in England and the United
Kingdom and in modern times in former British colonies, including the United States, Canada, and India. Plurality-based electoral systems are also called first-past-the-post and winner-takes-all systems.

With other rules based on the majority principle, if no alternative receives an absolute majority (more than half) of the votes, further rounds of voting are implemented, these rounds either requiring a simple plurality or reducing the choice to the two candidates with the highest numbers of votes in the first round. Such majority-runoff systems have traditionally been used in France, among other countries. A variant requires voters to rank all candidates, and includes several counts of votes (instead of several rounds of voting), until a candidate obtains the most preferences, as in the majority-preferential electoral system used in Australia (also called alternative vote or instant runoff).

Proportional representation in multimember districts allocates seats to multiple parties competing in an election on the basis of the votes received. The basic mathematical formulas that make this principle operable were invented in late eighteenth century for apportioning seats in the U.S. House of Representatives among differently populated states. These formulas were reinvented in Europe in late nineteenth century for the allocation of parliamentary seats to political parties with different numbers of votes. A proportional representation formula defines a quota of inhabitants or votes worth a seat. The “simple” quota (as devised by both Alexander Hamilton [1755/57–1804] and Thomas Hare [1743–1826]) is the divisor between the total number of inhabitants or votes and the total number of seats. But it usually requires an additional criterion to allocate some of the seats, most commonly to the largest remainders after the quota is used. In contrast, the smaller highest average or distributive number (as devised by both Thomas Jefferson [1743–1826] and Victor d’Hondt [1841–1901]) is sufficient to allocate all seats. This quota can be calculated after the election by several procedures, including trial and error, a series of divisors, or by lowering the simple quota until it fits.

Different forms of ballots may either force a categorical vote or permit some choice of individual candidates. Categorical ballots are used in single-member districts where voters can vote for only one candidate, as well as in multimember districts where voters can vote for only a closed list of candidates or en bloc. In contrast, open lists permit voters to select one or several candidates from a party list. With the double vote, voters choose both a closed party list and one individual candidate. The open ballot permits voters to vote for individual candidates from different parties. The majority-preferential vote and the single-transferable vote require voters to rank individual candidates.

**ELECTORAL SYSTEM CONSEQUENCES**

Elections in single-member districts by plurality or majority rule always produce a single absolute winner, who may have the support of only a minority of voters as a first preference. A winner by plurality or by second-round majority might be defeated by a losing candidate by absolute majority if a choice between the two were available. Majoritarian rules may thus induce nonsincere or “strategic” voting that favors the voter’s second-best or less-rejected candidate, so as to prevent the victory of a least-preferred one. In contrast, proportional representation electoral systems are more inclusive of several groups. Since most votes count to elect seats, they promote a more sincere revelation of preferences by voters.

In parliamentary elections with multiple single-member districts, plurality rule typically gives overrepresentation to one or two parties at the expense of others and fabricates a single party’s absolute majority of seats, thus permitting the formation of a single-party cabinet. In contrast, multiparty parliaments based on proportional representation tend to produce multiparty coalition governments based on a majority of seats and popular votes. In practice, there is a paradox: “majoritarian” electoral systems often create governments with minority electoral support, while proportional representation rules, which were initially devised to include minorities, tend to produce governments with majority electoral support. In plurality-rule electoral systems, a small change in the total number of popular votes can provoke a complete alternation of the party in government. Proportional representation systems, where parties may have opportunities to share power with different partners, produce more policy stability in the long term.

**THE CHOICE OF ELECTORAL SYSTEMS**

In general, the Micro-mega rule applies: the large prefer the small and the small prefer the large. Specifically, dominant and large parties prefer small assemblies and single-member districts that are able to exclude others from competition. In contrast, multiple small parties prefer large assemblies and large districts with proportional representation that can include them. Existing parties tend, thus, to choose electoral systems that are able to crystallize or consolidate the previously existing party configurations and systems.

However, the size of the assembly is a structural variable positively correlated to the country’s population and difficult to change dramatically. In large countries, such as Australia, Canada, France, India, the United Kingdom, and the United States, a large assembly can be sufficiently inclusive, even if it is elected in small, single-member dis-
Electra Complex

districts, due to the territorial variety of the representatives. In small countries, by contrast, the size of the assembly is small, and, as a consequence, the development of multiple parties favors more strongly the adoption of inclusive, large multimember districts with proportional representation rules. Proportional representation was first adopted for parliamentary elections in relatively small countries such as Belgium, Denmark, Finland, Netherlands, Norway, Switzerland, and other western European democracies in early twentieth century. In the long term, both the number of countries and the number of democracies in the world increase, while large countries decentralize, leading to an overall decrease in the size of democratic assemblies. This induces the adoption of more inclusive, proportional representation electoral rules.

In addition, the number of parties tends to increase under any electoral system as a consequence of the broadening of suffrage rights, as well as initiatives to politicize new issues and change the public agenda by groups seeking power or new policy decisions. Indeed, plurality rule provides incentives to form only a few viable large candidates or parties. But coordination fails with relative frequency, due to the costs of information transmission, bargaining, and the implementation of agreements among previously separate organizations. Lack of coordination may produce defeats and no representation for candidates, groups, and parties that have significant support among voters. Parties unable to coordinate themselves into a small number of candidacies to compete successfully under plurality rule tend to choose electoral systems that can reduce the risks of competing, giving all participants greater opportunities to obtain or share power.

There is, thus, a general trend toward proportional representation over time. Nowadays, most democratic countries in the world use electoral systems with proportional representation rules. Likewise, for presidential elections, plurality rule tends to be replaced with second-round majority rules permitting multiparty competition in the first round. Many countries have also introduced a greater element of individual candidate voting. In fact, none of the new democracies established in countries with more than one million inhabitants in the “third wave” of democratization (since 1974) has adopted the old British model of a parliamentary regime with elections in single-member districts by plurality rule.

ELITE THEORY

“Classic” elite theories were formulated at the end of the nineteenth century and in the first decades of the twentieth century by Vilfredo Pareto (1848–1923), Gaetano Mosca (1858–1941), and Robert Michels (1876–1936). Subsequent renditions of these theories also carried a strong imprint of Max Weber’s ideas, especially concerning the centrality of political power and charismatic leadership.

The classic theorists focused on the inevitability of a group of powerful “elites” in all large-scale societies, offering a radical critique of two competing theoretical-ideological streams of thought: the democratic theory (“government of the people, by the people, for the people” in Lincoln’s Gettysburg Address), and the Marxist vision of class conflict leading to revolution and egalitarian socialism. In contrast with both of these ideologies, the elite theories suggested an inescapable division between dominant minorities (variously called “elites,” “ruling classes,” “political classes,” “oligarchies,” “aristocracies,” etc.) and the dominated majority, or the “masses” (Bottomore, 1993).
Mosca saw this inevitable polarization of power as reflecting a “material, intellectual, or even moral superiority” (1939, p. 50) of ruling minorities, with their small size and organizational skills helping to maintain this position; Pareto anchored elite domination in the talent and psychological dispositions of such groups, combined with the skilled use of force and persuasion; and Michels saw the domination of “oligarchies” as the necessary outcome of large-scale organization. All three agreed that political power, and not property, forms the foundation of social-political hierarchies, and that these hierarchies can neither be reduced to nor deduced from economic class relations. Most importantly, elite theorists insisted that there could be no escape from elite power: revolutions merely mark elite circulation and, as illustrated by the Russian Revolution, do not narrow the power gap between the elites and the masses. Egalitarian political order and participatory democracy are, therefore, ideological dreams. History, observed Pareto, is a graveyard of successive elites or “aristocracies” ([1915] 1963, p. 1430).

Elite theories can also be seen as an intellectual response to the “modern trends” that strengthened the state and have led to the rapid expansion of government bureaucracies, the emergence of bureaucratized mass parties, the concentration of corporate power, the growth of powerful and centralized mass media, and the rise of fascist and communist movements and regimes—all of which have weakened liberal capitalism and dented the hopes for participatory democratization. Mosca, Pareto, Michels, and Weber all saw these trends as a consequence of bureaucratic industrialism. In their view, the increasing complexity of modern society implied progressive bureaucratic organization of all activities and power concentration in the hands of elites, who can effectively manage democratic institutions, accumulate the privileges that power brings, orchestrate mass support, and protect their positions by controlling access to the top. This view of power stratification, combined with the insistence on the universality of elites and treatment of elite characteristics as key explanatory variables, constitutes the most distinctive tenet of classic elite theory.

The second theoretical tenet concerns the capacity of power holders to organize themselves and form cohesive groups. Strong cohesion does not preclude the possibility of temporary intra-elite conflicts and divisions on specific policy questions. However, when it comes to defending common power interests, members of the elite act in unison, and this makes their power irresistible.

The third tenet concerns the linkages between elites and various “social forces,” such as social movements, classes, and ethno-racial groups. The classic elite theorists insist that such linkages are an essential condition of elite power, but they are less than clear on precise meaning of such linkages.

The fourth tenet is about access and succession. Entry to the elite ranks depends on acquiring certain rare attributes (e.g., wealth, prestige, education), and it is carefully controlled—directly and indirectly—by elite incumbents. Elites control recruitment of their successors through institutional “gatekeepers” (e.g., corporate hierarchies, political party machines) as well as through elite “selectorates” operating at each level of hierarchical promotion. One outcome of these selective practices is a biased social composition; another is a persistence of elite outlooks, even at times of rapid social mobility and elite circulation, that is, replacement of elite members.

The final tenet highlights the way in which elites typically exercise their power. All elite theorists converge on a view of “engineered” elite domination through persuasion and manipulation, occasionally backed by force. Democratic elections have a symbolic character and are an important tool for the orderly circulation of elite personnel, but they seldom alter elite structure.

The post–World War II (1939–1945) students of elites played down the cohesion of elites and questioned the classic theorists’ skepticism as to the prospects for democratization. In the seminal formulation of Joseph Schumpeter (1954), elites are an essential ingredient of modern democracy, which implies a regular electoral competition for political leadership. This idea was followed up by Robert Dahl (1971), Giovanni Sartori (1981) and many other “plural,” “demo-,” and “neo-” elite theorists.

It was backed by empirical studies of modern elites (summarized by Robert Putnam in 1976), especially in advanced democracies, that revealed complex networks of competing and collaborating elite groups, rather than cohesive minorities. The key question was whether elites (mainly in the United States) formed a cohesive and unsailable “power elite” or more open, competitive, and responsive “plural” or “strategic” elite groups. The results of these studies, however, were inconclusive, largely because any picture of power distribution depends on the way power is defined and measured. Those who identified power holders by their reputation and incumbency in top organizational positions produced a picture of cohesive “establishments” and “power elites.” In contrast, those who defined elites as key decision makers produced a picture of “plural” elites, that is, competing elite groups.

Contemporary elite theorists, especially those studying postcommunist transformations, transcend these debates, incorporate elites into broader power and stratification schemes, acknowledge the complexity of power sources and structures, and analyze elites as important “crafters” and “sustainers” of democratic regimes. Perhaps the best-known theoretical syntheses of the class and elite
visions of the power structure were undertaken by Wlodzimierz Wesolowski and Eva Etzioni-Halevi, who both saw elites and classes as being linked. In this view, elites enter into alliances (via “coupling”) with major classes and other “social forces.” As mentioned above, elites are defined in political terms as the most powerful minorities, while classes are defined in economic terms as owners or workers. The relations between elite and regime types of power (including postcommunist regimes and established liberal democracies) have been explored by John Higley and his collaborators (e.g., Field and Higley 1980; Higley and Pakulski 1995; Higley and Burton 2006), who have focused on two elite characteristics—structural integration and value/normative consensus—as key determinants of political stability and democratic character of regimes. Only consensually united elites—that is, elites characterized by inclusiveness and open access (wide integration), as well as strong and widely shared agreement about the norms of political behavior (“rules of the game”)—can sustain stable liberal democracies. Elites united by ideological formulas (e.g., the Chinese) operate stable but undemocratic regimes, while disunited elites accompany—and perpetuate—unstable regimes.

ELITES

The term elites refers to a small number of actors who are situated atop key social structures and exercise significant influence over social and political change. Much of the power of elites stems from their economic resources, their privileged access to institutions of power, and their ability to exercise moral or intellectual persuasion. At the same time, however, elites embody the values and represent the interests of particular groups in society. This can limit their autonomy, complicate efforts to cooperate with each other, and narrow the support they elicit from the public.

It is this contradictory aspect of elites—simultaneously empowered and constrained by their positions as leaders in society—that defines their role in the political system.

While traditional notions of elites have typically focused on members of an aristocracy (or oligarchy), whose positions were based on claims to hereditary title and wealth, elites today comprise key figures across various sectors of society. In and around government, they include political leaders within the executive and legislative branches of government, those in command of the bureaucracy and military, and leading representatives of organized interests in society (such as labor unions or corporate lobbying groups). Within the economy, elites reside at the pinnacle of finance, banking, and production. In the cultural sphere, elites include major patrons of the arts, cultural icons (including pop culture), writers, academics, religious leaders, and prominent figures within the mass media. Most recently, transnational elites have arisen within emergent supranational institutions, such as corporate actors in the World Economic Forum, technocrats working in the United Nations system, and the heads of international nongovernmental organizations.

EVOLUTION OF THE TERM

Although the idea of elites can be traced back to the writings of Aristotle and Plato, the term elites was first used in modern social science by the Italian economists Vilfredo Pareto, Vilfredo. [1915] 1963. A Treatise on General Sociology. New York: Dover.

Pareto (1902–1903) and Gaetano Mosca (1939) in the early twentieth century. In contrast to class theories, in which the sources of societal power inhered in institutions of property and class relations in society, early elite theories saw power concentrated among a minority of the population who were able to rule over the rest of the population with little accountability to them. As a result, elites were often conceptualized as “ruling elites,” by virtue of their authority over the masses. As critics noted, however, the origins of elite power were underspecified. It was not clear, for example, if elites were inevitable products of modern organization, or if their position was contingent on their ability to control vital resources in society and mobilize the public.

In 1915, in his book Political Parties, the German sociologist Robert Michels introduced the “iron law of oligarchy.” Michels contended that the existence of elites sprang from an inherent tendency of all complex organizations to delegate authority to a ruling clique of leaders (who often take on interests of their own). Accordingly, even the most radical organizations will develop a self-interested elite. In a prominent 1956 study of the United States, C. Wright Mills proposed that elite power was defined by its institutional origins. Mills argued that the place of a “power elite” was maintained by their positions in government, the military, and major corporations, which enabled them to command the organized hierarchies of modern society. While these and other works of the time, including Joseph Schumpeter’s 1954 “competitive elitist” account of democracy, demonstrated the importance of the organizational bases of elite power, the origins of elites are more socially contingent on factors such as patronage and factionalism, leadership, and social structure than on institutional structure. Nonetheless, this classic work has heavily influenced elite studies, particularly scholars studying intra-elite political struggles within East bloc countries (through work termed “Kremlinology”).

Distinguishing themselves from these classical theorists, scholars since the 1960s have begun to differentiate elites and recognize their diverse roles. Major works, such as Suzanne Keller's Beyond the Ruling Class (1963), have traced elites' sociological origins, examined their varied social functions, and engaged in empirical studies of a range of actors at the apex of almost any area of human activity. In contrast to classical approaches, these authors have highlighted ways in which elites conveyed societal claims upon the state. While this opened new avenues of research, their tendency to rely on the social profile of elites (such as age, education and occupation, and region or country of birth) at times produced inaccurate predictions of elite behavior. Though influential in shaping latent political attitudes, empirical research has shown that background characteristics are mediated by personal beliefs and values. As scholars such as Robert D. Putnam (1976) have concluded, the attitudes and political styles of elites do affect political outcomes, but behavioral patterns must be placed in a context of elite linkages to different social strata.

There has also been considerable cross-national variation in the openness of elites. In many societies, the elite manipulation of political patronage and the organization of political parties have perpetuated elites’ positions. In some countries, however, government programs have been designed to desegregate elites (though the success of these programs has been limited). As Richard L. Zweigenhaft and G. William Domhoff demonstrated in Diversity in the Power Elite (1998), affirmative action initiatives within the United States have led to some openness along racial, gender, and class lines. However, they also showed that minorities and women absorbed into the elite often minimize their differences and, paradoxically, strengthen the existing system. Thus, government reforms (in the United States and elsewhere) seeking to enhance the diversity of elites have not produced the expected or hoped for results.

**ELITES AND THE POLITICAL SYSTEM**

As suggested in foundational studies of elites, the importance of elites to the political system is heavily affected by struggles within ruling cliques and by elites’ relationships to social structures. Although elites influence the political system in numerous ways, the focus here will be on their effects on political regimes and democracy, the politics of state development, and incidences of violent conflict.

The nature of competition and compromise among ruling elites carry major implications for democracy. Although pluralist theory suggests that the dispersion of power in democratic systems across interest groups and institutions leaves elites in charge of different sectors of democratic politics, elites have a coordinated effect in mobilizing public opinion and ushering in political change. In The Nature and Origins of Mass Opinion (1992), John Zaller describes how, even in established democracies, elites attempt to construct a political world through messages delivered via media outlets to the mass public. In nondemocratic regimes, concentrations of power within ruling circles means that stability and prospects for political change hinge on the skill and engineering of elites, who can negotiate compromises between competing factions. Indeed, it has been long held that elite failures to rise above societal divisions can contribute to the rise of extremist politics, as typified by the rise of Nazism in interwar Germany. As Dankwart A. Rustow (1970) and more recently John Higley and Michael Burton (1989) have argued, democratic elites must not only establish a language of compromise across factions, but also accept the boundaries of political competition,
and become habituated to the rules of the game. Recent studies, however, have shown that extremist popular mobilization can coexist with elite negotiations, and that the success of democratic transition depends not on moderation per se, but on elite calculations and projections of whether the forces of political change—moderate or extremist—will threaten their interests after they cede power (Bermeo 1997).

In addition to power struggles within ruling circles, the struggle between rulers and local elites has been crucial in centuries-long efforts to complement states’ juridical sovereignty with empirical statehood. As much of western European history attests, nobles, magnates, and landlords (among others), supported by property holdings and large armies, posed substantial challenges to the centralization of state power. Initially, future sovereign rulers were little more than members of the elite, as illustrated by Perry Anderson’s reprint of the famous oath of allegiance among Spanish nobility: “We who are as good as you swear to you who are no better than we to accept you as our king and sovereign lord, provided you observe all our liberties and laws; but if not, not.” (Anderson 1974, p. 65) Such diffuse systems of authority under local societal elites are also found in many “weak states” in contemporary Asia, Africa, and post-Communist Eurasia. Both historically and today, therefore, the emergence of effective state infrastructures depends on whether mixtures of coercion and patronage dispensed by rulers convince entrenched elites to cede political authority.

A final realm of politics in which elites play a critical role is violent conflict within society. In particular, intra-elite politics and elite-mass linkages reside at the center of civil wars, and elite power-sharing models have been applied across a diversity of contexts. Among the most well-known is Arend Lijphart’s “consociational” model (1977), which claims that a coalition of elites, drawn from the conflicting sides, can mitigate violence through a system of elite consensus built on mutual veto power, proportional allocation of offices, and granting each group partial autonomy. The success of such negotiated pacts has been variable, deterring violence in the Netherlands and in post-apartheid South Africa but failing to prevent an explosion of intra-state conflicts in the immediate post–cold war period. Ultimately, the prevention or cessation of violence is causally related to how elites interact with one another and how effectively they channel societal claims through political institutions.

**ELITISM**

Elitism refers to the belief that leadership positions within a society, or in government more specifically, should be held by those possessing the highest levels of education, wealth, and social status. According to elitism, a select subgroup should make or influence decisions for the whole society. Overall, elitism as an ideology advocates that select citizens are best fit to govern.

First noted in Western philosophy by Socrates (c. 470–399 BCE), who described the good society as one headed by philosopher kings, elitism is distrustful of the masses and is in clear opposition to egalitarian or pluralis-
tic principles. Contradicting democratic theory, elitism contends that the capacity to effectively control a dynamic and multifaceted political arena is absent in the average citizen and should be reserved only for a limited few. Thus elitism defers to those individuals whose backgrounds and experiences are believed to make them superior. Depending on the society in question, superiority can be based on perceived intellectual aptitude, skin color, or other factors. Most commonly, characteristics of the elite include educational achievement, family background, and economic affluence. In some societies ethnic heritage, religious affiliation, or gender are the basis of a classification system that distinguishes the elite from the nonelite. In sum, elitism can be defined as an asymmetrical relationship in which a select few, who are considered superior, exercise control over the many, who are considered inferior.

In practice, elites pervade most societal institutions in industrialized Western democratic nations, according to Jack C. Plano and Milton Greenberg (1997). Elites may wield significant influence in such specific arenas as commerce, the military, and government operations. Sociology and political science scholarship has analyzed the role of elites in decision-making processes in various institutional settings. A seminal work by the sociologist C. Wright Mills (1916–1962), *The Power Elite* (1956), argues that a single elite, rather than a variety of competing groups, makes key decisions for the nation as a whole. The governing elite includes political leaders, corporate leaders, and military leaders.

Due to its advocacy of the virtues of the select over the “commoners,” elitism as a normative theory often comes under fire for its antidemocratic tendencies. Critics argue that elitism leads to corruption, greed, intolerance, racism, and other undesirable social outcomes. Many political reform movements have been defined by their desires to eliminate elitist political structures. The historian Richard Hofstadter (1916–1970), in his book *The Age of Reform*, gives as an example of antielitism the late nineteenth-century populist movement in the United States. The populists, he argues, believed in the “people versus the interest, the toiling multitude versus the plutocrats, the making groups, makes key decisions for the nation as a whole. The governing elite includes political leaders, corporate leaders, and military leaders.

Mexico, and Japan. Nativist concerns about the new immigrants led to escalating pressures for a federal immigration policy.

The new federal immigration station that opened in 1892 on Ellis Island was a key component of the new federal immigration policy, which set standards for minimum health and competency, regulated the process of inspection and deportation for overseas immigration, and delegated enforcement to a superintendent of immigration and an Office of Immigration, located within the Department of the Treasury, later Commerce, and then Labor, until 1940, when the Immigration Service was transferred to the Department of Justice. Ellis Island was the entry point for twelve million people, about three-fourths of the migrants who entered the United States between 1892 and 1924. On its busiest day, April 17, 1907, Ellis Island officials processed 11,747 immigrants. Other federal immigrant processing stations were established at Boston, Philadelphia, Baltimore, and at Angel Island in San Francisco Bay.

Many European immigrant accounts of their experience at Ellis Island emphasized the hopefulness of arrival and the often confusing and sometimes frightening aspects of inspection. Steerage passengers entering New York Harbor boarded ferries for Ellis Island (American-born passengers and those travelling first and second class were examined on board ship). After being tagged with their number from the ship’s official listing, immigrants walked into the baggage room where they were encouraged to check their belongings. Then they moved up the steps to the second-floor registry room in the Great Hall, where they were evaluated by medical inspectors looking for contagious diseases and physical disabilities, and by legal inspectors checking that names, birthplaces, ages, and occupations matched ship registries and ascertaining that immigrants were not likely to become wards of the state. Stories from prior travelers helped immigrants rehearse answers for the inspectors, and provided strategies for passing through successfully, for example, discretely passing the same twenty-five dollars from immigrant to immigrant to preempt the requirement for proving self-support. A literacy test for immigrants over fourteen was administered after 1917.

The shipping lines had to bear the cost of returning “excluded aliens” to their point of departure. Most newcomers, 80 percent or more, passed through the process successfully; detention for the remaining 20 percent, for legal or medical reasons, lasted in most cases less than two weeks. Although most of the patients held in medical detention recovered and were able to complete the immigration process, between 1900 and 1954, over 3,500 people, including 1,400 children, died on Ellis Island. Historians have calculated that despite a growing number of excludable categories, only about 2 percent of Ellis Island migrants failed to gain entry. In comparison, Chinese immigrants trying to gain entry through Angel Island by making use of the very few exceptions provided by the Chinese exclusion laws faced much more rigorous interrogation and isolation, and much lengthier detentions.

Ellis Island’s functions changed dramatically with the passage of immigration restriction in the 1920s, ending the era of open European immigration. Combined pressures for exclusion proposed by white Anglo-Saxon Protestant restrictionist groups, reinforced by theories of scientific racism spurred by World War I (1914–1918) rhetoric of “100 percent Americanism,” the Red Scare’s linking of foreigners with radicalism, and the labor movement’s fears of rising unemployment, resulted in the passage of the Quota Act in 1921 and the Johnson-Reed Act in 1924. The Quota Act limited the total number of immigrants who could enter the United States and required that immigrants bring passports. The Johnson-Reed Act did not limit immigration from the Western Hemisphere, but it reduced the total number of entering immigrants, and most significantly, established national-origins quotas to favor northern and western European immigrants, who received 82 percent of the annual total quota allotted. The Johnson-Reed Act also expanded the category of illegal aliens, reaffirming the principle of Chinese exclusion and barring Japanese and other immigrants from the “ Asiatic Zone,” defined in 1917 as stretching from Afghanistan to the Pacific, on the legal grounds of their exclusion from citizenship.

By the 1920s, Ellis Island officials were processing far fewer arrivals and were no longer providing medical or mental exams or housing immigrants who were ill, since the passport and visa requirements relocated many aspects of verification and inspection from Ellis Island back to the country of origin. During the 1930s, nearly as many people left as entered the United States, and Ellis Island officials processed some immigrants returning to Europe. During World War I, Ellis Island became a temporary detention center for “enemy aliens,” and in 1919 radicals rounded up by Attorney General A. Mitchell Palmer (1872–1936) and housed incommunicado prior to deportation included the Russian anarchist activists Emma Goldman (1869–1940) and Alexander Berkman (1870–1936). Ellis Island was increasingly used for detention and deportation of “aliens.” By the 1930s, the people detained on the island were undocumented immigrants without passports or visas, foreign-born criminals awaiting deportation, and sick merchant mariners receiving treatment at the hospital.

During World War II (1939–1945), “enemy aliens” were again held on the island. After 1950, immigrants sus-
pected of being communists were denied entry or detained awaiting deportation, including the West Indian Marxist writer C. L. R. James (1901–1989) in 1952. Despite the needs of the many refugees created during World War II, the restrictive immigration laws kept the numbers of European immigrants very small. Ellis Island was finally abandoned by the Immigration and Naturalization Service in 1954 and classified as surplus property. President Dwight D. Eisenhower’s (1890–1969) General Services Administration tried unsuccessfully to sell Ellis Island and its buildings to the highest bidder in 1956. President Lyndon B. Johnson (1908–1973), who traveled to the Statue of Liberty to sign immigration reform in 1965, granted landmark status to Ellis Island as part of the Statue of Liberty National Monument within the jurisdiction of the National Park Service. New interest in historic preservation and in European-heritage ethnicity generated popular and public support for the restoration and reopening of Ellis Island as an immigration museum in 1990.

EMOTION
Over the last three decades, the sociology of emotions has developed a number of distinct theoretical and research programs (for recent reviews, see: Turner and Stets 2005, 2007; Stets and Turner 2006). While there is considerable overlap among some perspectives on emotions in sociology, they can be roughly grouped into six basic approaches: (1) dramaturgical and cultural, (2) ritual, (3) symbolic interactionist, (4) exchange, (5) structural, and (6) evolutionary.

Dramaturgical and cultural approaches all draw upon the early insights of Goffman (1967), who argued that human interaction is very much like a performance on a stage. Like all stage performances, there is a script—in this case written by cultural ideologies and norms of a society—with actors engaging in strategic performances as they interpret the script and use props to make a dramatic presentation of self to an audience. Hochschild (1983) was the first to adopt elements of this metaphor by analyzing how the cultural script, social structure, and audience expectations force individuals to manage emotions that they do not feel. As a consequence, individuals must engage in “emotion work” that is inherently alienating. Other researchers have stressed how individuals use cultural scripts as a cover for more strategic performances in games of micropolitics and microeconomics (Clark 1997).

Ritual approaches draw from Durkheim’s analysis of “collective effervescence” and emphasize that when individuals are co-present, the dynamics that ensue can build up positive and negative emotional energy that, ultimately, is the energy driving the formation, reproduction, and change of social structures and culture (Collins 2004). When initial greeting rituals arouse mild positive sentiments, subsequent talk and body language become rhythmically synchronized, leading to emotional entrainment and heightened emotions that increase social solidarity, which, in turn, is represented with group symbols. When these processes fail, negative emotional energy is aroused, thereby lowering solidarity.

Symbolic interactionist approaches all emphasize the central place of self in arousing emotions (Stryker 2004; Burke 1991). When self is verified by others, positive emotions ensue, whereas when self is not confirmed, negative emotions are aroused. Self is seen as a cybernetic control system in which individuals seek to maintain consistency among cognitions about self, behavior, situation, and other; discrepancies between any of these cognitions lead to negative emotional arousal that serves as the motivation to change the self presented, behaviors, definitions of the situation, or assessments of others (Heise 1979). Psychoanalytic variants of symbolic interactionism emphasize that individuals often protect self through the activation of defense mechanisms, which push the negative emotions, such as shame, below the level of consciousness (Scheff 1988). Once repressed, the emotions are transmuted into new kinds of more intense negative emotions (Turner 2002).

Exchange approaches view social interaction as the reciprocal flow of resources. Individuals seek to gain a profit in all exchanges by assessing whether or not their rewards exceed costs and investments. When individuals see that their and others’ shares of resources are proportionate to respective costs and investments, they experi-
ence positive emotions; and when they do not, negative emotions are aroused (Lawler 2001). People always compare their receipt of resources to cultural standards of justice. When actual shares of resources meet standards of what constitutes a “just share,” positive emotions are experienced; when shares do not correspond to perceptions of a “just” share, negative emotions are aroused (Homans 1974; Jasso 1980). The positive emotions in profitable exchanges become yet another resource to be exchanged and lead individuals to make suboptimal commitments (or less than maximum payoffs) to social relations that increase solidarity (Lawler and Yoon, 1996).

Structural approaches see interaction as revolving around the distribution of power and prestige, with individuals having expectations for how much power or prestige they can claim in a situation (Kemper 1978; Ridgeway and Johnson 1990). When these expectations are realized, positive emotions ensue, but when there is competition for status and/or prestige or when a person does not receive anticipated prestige or power, negative emotional arousal among some actors will ensue. Moreover, once the distribution of power and prestige is established, expectations operate to sustain this distribution, and the emotions generated become yet another expectation state.

Evolutionary approaches seek to outline the selection pressures that operated on humans’ hominid ancestors to produce the neurological structures responsible for emotional arousal (Wentworth and Yardly 1994; Turner 2000; Hammond 2004). Although these approaches vary in terms of how much they see biology as determining specific emotional responses, they all emphasize that the human brain was rewired under intense selection pressures that operated on humans’ hominid ancestors to produce the neurological structures responsible for emotional arousal among some actors will ensue. Moreover, once the distribution of power and prestige is established, expectations operate to sustain this distribution, and the emotions generated become yet another expectation state.

Although these approaches vary in terms of how much they see biology as determining specific emotional responses, they all emphasize that the human brain was rewired under intense selection pressures that produced the neurological structures responsible for emotions.

As is evident, then, the sociology of emotions has grown enormously from its tentative beginnings in the 1970s. There is a broad set of approaches, each with a coherent body of theory and most with active research programs testing and extending these theories. The sociology of emotions is now the leading edge of sociological social psychology and microsociology in general.

EMOTION AND AFFECT

Emotions are central to one's personal and social life, and they have been an important topic in psychology throughout history. The terms mood and emotion are often used interchangeably to refer to certain aspects of affect. But while there are similarities, mood and emotion are fundamentally different. For example, emotions appear to have a particular cause and are short-lived. They are psychological experiences that involve the interplay of cognitive, physiological, and expressive behavior. In contrast, psychologists define affect as an individual's externally displayed mood. Typically people feel some level of positive affect and some level of negative affect in their daily life.

CATEGORIES AND TYPES OF EMOTION

Although psychologists and philosophers have discussed emotions for years, debates continue about what constitutes an emotion and how different emotional experiences should be classified. In 1990 Andrew Otrony and Terence Turner summarized a list of the basic emotions that had been compiled by a wide variety of researchers. In general nearly everybody who postulates basic emotions includes anger, happiness, sadness, and fear. In addition there are two main approaches in proposing basic emotions. The biological view suggests that emotions can be understood in terms of their evolutionary origin and significance and that this knowledge can contribute to understanding the function of emotions. The psychological view suggests that there might be some small, basic set of emotions on which all others are built. Basic emotion classification has been useful in explaining how emotions evolve and exist in all cultures.

Another way to classify emotions involves whether they are discrete categories or continuous dimensions. Categorical models focus on a number of discrete emotions (e.g., basic emotions). In contrast, dimensional models typically focus on varying levels of self-reported feelings on a particular dimension varying from positive to negative. Categorical and dimensional models are often discussed separately, but they are not necessarily incompatible. For example, the discrete emotion of happiness corresponds with high activation and pleasantness (positive valence), whereas the discrete emotion of sadness corresponds to low activation and low pleasantness (negative valence). Researchers can employ both models of categorizations, or they can advantage one over the other.

THEORIES ON EMOTION AND AFFECT

Historically the James-Lange theory was independently proposed by William James and Carl Lange in the 1880s. Together they argued that emotion is the perception of physiological changes in the body. For example, a person experiences fear because he or she perceives physiological changes, such as an increase in heart rate and breathing, muscle tension, and sweat gland activity. In 1927 Walter Cannon and Philip Bard criticized this theory, suggesting that an individual experiences an emotional event first, after which more information is collected through one's senses. This additional information is sent through the nervous system to the brain, where a message is sent to the cortex, thereby producing a specific emotion, and to the hypothalamus, which controls the body's responses, such as crying or laughing.

In 1962 Stanley Schachter and Jerome Singer proposed that there were two factors that determine different emotions: the physical changes in a person's body in response to an event or stimulus and the interpretation that the person gives to those changes. An important assumption in the Schachter-Singer view is that once an emotional feeling has been produced, that particular feeling can cause specific actions. There has also been considerable theoretical and empirical work attempting to identify specific cognitive dimensions that shape the emotional response. In 1990 Richard Lazarus and Craig Smith described a specific appraisal model detailing the specific cognitive evaluations that are associated with (and hypothesized to be causally antecedent to) the experience of a number of distinct emotions.

Although these and many other emotion theorists have postulated and tested their ideas, there are many aspects of emotion that are still untested and undiscovered. New advances in neuroscience will allow researchers to observe physiological characteristics that are more objective compared to cognitive appraisals. A number of noninvasive techniques have been developed to measure physiological responses, such as heart rate reactivity, skin conductance, and cortisol levels with greater accuracy. Researchers can also study an individual's response to emotional stimuli and record the individual's expression of emotion. Concurrent measures of physiological, cognitive, and expressive behaviors of emotion allow researchers to study emotions in a more complete and dynamic way.

RELATIONS TO DEVELOPMENTAL OUTCOMES

The experience of emotions has significant psychological and physiological effects. How people interpret their experience motivates and guides their actions and specific behaviors. Emotions convey to others what the individual is feeling, and they may also help regulate social interactions. Several studies have demonstrated that children's understanding of emotions, awareness of emotional states, and emotion regulation are associated with children's...
socio-emotional competence and coping skills. Social competence in turn is associated with positive development in areas such as peer acceptance, school achievement, and emotional well-being. Nancy Eisenberg has suggested that sympathy (concern for others based on the apprehension of another’s state) and empathy (an emotional reaction elicited by and congruent with another’s state) stimulate the development of internalized moral principles reflecting concern for other people's welfare. Indeed in a 1999 study Eisenberg and colleagues found a relation between sympathy and empathy and prosocial behavior.

Some research indicates that an inability to express and interpret emotions in socially appropriate ways may lead to maladaptive behaviors, such as aggression and social withdrawal. For example, even though anger can serve to regulate interpersonal behavior, it comes to be regulated in an interpersonal context through socialization. The individual has to learn when and how to express anger in culturally acceptable ways. Problems in emotion regulation and the expression of anger are implicated with failures in social interaction (see Lemerise and Dodge 1993), while difficulty in the regulation of anger is further reflected in psychopathology (see Dodge and Garber 1991). Thus the ability to modulate and express emotions is associated with a variety of maladaptive and adaptive developmental outcomes.

EMOTION REGULATION

The study of emotion regulation is a burgeoning subfield within the modern social sciences. It explores how individuals influence the emotions they have, as well as when and how they experience and express their emotions. Whereas an emotion refers to a brief response to an internal or external event, emotion regulation is the process by which individuals influence the intensity, duration, valence, or manifestation of that response. Some researchers argue that all emotions are inherently regulated, so that emotion need not be distinguished from emotion regulation.

Emotion regulation is distinct from coping, insofar as coping focuses primarily on decreasing a negative emotional experience. Emotion regulation, in contrast, can include increasing or decreasing both positive and negative emotions. Emotion regulation may be conscious or unconscious, it may reflect controlled or automatic cognitive processes, it may occur at multiple time points in the course of an emotional response, and it may exert a multiprong effect on numerous facets of emotion (i.e., subjective experience, behavioral expression, physiological response).

Early interest in the field of emotion regulation can be traced back to Freudian psychoanalytic perspectives on unconscious anxiety regulation, as well as to the early stress and coping literature. Contemporary perspectives now rely heavily on James Gross’s process model of emotion regulation (1998), in which he distinguishes between antecedent-focused strategies, which occur before an emotion is generated, and response-focused strategies, which are aimed at altering an already existing emotion by increasing or decreasing the experience, outward behavior (such as by suppressing), or physiological response. Antecedent-focused strategies include situation selection, situation modification, attentional deployment, and cognitive change (i.e., reappraisal). Situation selection refers to
either approaching or avoiding specific places, people, or objects in order to alter their emotional impact. Attentional deployment is used to alter a specific aspect of a situation by focusing one's attention toward it. Cognitive change has gained increasing attention in cognitive therapies as a means to alter a person's emotional response upstream by changing the way one thinks about a given situation. Response-focused strategies include any act that influences one's ongoing experience of behavioral or physiological emotion response. An example includes behavioral suppression, or the dampening of one's outward displays of emotion (such as trying to constrain facial expressions of happiness).

ADAPTIVE AND MALADAPTIVE EMOTION REGULATION STRATEGIES
Researchers have begun to examine whether some types of emotion regulation strategies are more adaptive than others. Initial evidence demonstrates that reappraisal is an adaptive strategy associated with improved social functioning, positive emotion, and well-being. Suppression, by contrast, is a maladaptive strategy associated with elevated levels of negative affect and decreased positive affect. The chronic use of maladaptive strategies is thought to represent a core mechanism underlying numerous clinical disorders, ranging from binge eating and schizophrenia to bipolar disorder and generalized anxiety. In a 2004 paper, Ann Kring and Kelly Werner highlight two ways in which clinical disorders might represent difficulties regulating strong feelings; namely, through either emotion dysregulation, which involves the inappropriate use of otherwise intact regulatory processes, and problems in emotion regulation, involving an absence or deficit of basic regulatory processes. Whereas emotion dysregulation might involve an individual who is able to reappraise but simply does not implement his or her skills in the appropriate context, problems in emotion regulation refers to profound deficit in the requisite skills of reappraisal. Additional research is needed to examine the ways different clinical disorders represent such impairments, and whether such difficulties are transdiagnostic.

EMOTION REGULATION AND DEVELOPMENT
Developmental psychologists have given extensive treatment to the study of emotion regulation in infancy. Temperamental differences in emotion regulation have suggested that children have innate differences in the threshold to elicit positive or negative emotions as well as differences in the capacity to self-soothe, an important regulatory strategy. Emotion regulation is learned early in life largely by external agents such as caregivers. Joseph Campos, Carl Frankel, and Linda Camras argue that the infant and caregiver represent a “coregulatory system,” and that early in development the parents’ expressive behaviors serve as powerful regulators of a child’s current emotional state. Children often synchronize and coordinate the expressions of their caregivers as a means to learn how to appropriately express feelings in given contexts. However, as the infant develops, he or she becomes increasingly less reliant on the caregiver and more independent in the initiation and control over regulating his or her feelings. With further age advancement, research across the lifespan suggests people also become more effective in regulating their own feelings as they age.

EMPATHY
Although definitions of empathy vary, the word is frequently defined as a vicarious emotional reaction based on the apprehension or comprehension of another’s emotional state or condition. Inherent in this definition is that this reaction is identical or very similar to what the other person is feeling or would be expected to feel in the situa-
tion. Indeed, empathy may often be the origin of other related emotional reactions. In many situations, for example, empathy is likely to turn into either sympathy or personal distress. Sympathy is an emotional reaction based on the apprehension of another's emotional state or condition that involves feelings of compassion, sorrow, or concern for another person, rather than feeling merely the same emotion as the other individual. Sympathy is believed to involve an “other” orientation and the motivation to assist the other person, whereas empathy by itself does not. However, empathy may also turn into personal distress—an aversive, self-focused emotional reaction (such as anxiety or discomfort) to another’s emotional state or condition. Personal distress is associated with a focus on “self,” with a desire to make the self, not the other person, feel better. Sympathy, on the other hand, tends to be related to other-oriented altruistic behavior, particularly when it is not easy to escape from the need or distress of the other person, or from social sanctions for not helping. Moreover, inducing adults to feel sympathy for a stigmatized group improves attitudes toward the group as a whole.

Empathy and sympathy appear to increase with age in childhood, but they may stabilize by mid- to late adolescence. Sympathy is not only related to engaging in prosocial behaviors such as helping and sharing, it is also correlated with high levels of social competence, low aggression in children, and measures of psychological adjustment. Females tend to score higher in sympathy and empathy than males, especially if the measure is self-reported or other-reported. Girls tend to display more concerned behaviors than boys, but there is no gender difference in males’ and females’ physiological reactions to empathy-inducing stimuli. Thus, males and females may respond similarly to empathy-inducing stimuli but interpret or react differently to them (Eisenberg and Fabes, 1998).

Empathy appears to have a biological basis. Identical twins, for example, tend to be more alike in empathy and sympathy than are fraternal twins. However, the familial and larger social environment appears to affect individual differences in empathy and sympathy. People tend to be more empathic or sympathetic if they are securely attached to their mother and if their parents are sympathetic, supportive, and warm in their parenting. In addition, parental expression of positive emotion in the family, parental discussion of emotion, and parental use of reasoning that emphasizes the effects of children’s behavior on others (and helps them to take the perspective of another) have been associated with the development of sympathy (and often empathy) in children. The expression of hostile negative emotions (e.g., anger) in the home has been associated with low levels of sympathy in children, but this association may not hold by adolescence. Finally, because self-regulation is associated with being sympathetic, parenting practices that foster the regulation of emotion and behavior appear to promote the development of sympathy.

EMPIRE

Empire, imperial, and imperialism are terms with complex and contested histories: one is even tempted to think of them as essentially contested concepts in the philosophers’ sense. In the political discourse of the twentieth century’s second half, they were well-nigh always used pejoratively. Almost nobody, and no state, was willing to adopt them as self-descriptions. The idea of empire has often been associated, sometimes in emotive or polemical style, with particularly aggressive, coercive, expansionist, hierarchical, and indeed racist forms of power. Such associations have been yet more widely perceived in relation to imperialism, a term whose uses have tended to be more monolithically pejorative than have those of empire.

THEORIES AND POLEMICS

The concept of empire has also tended, at least until recently, to be far more widely employed and debated among humanities scholars—especially, and naturally enough, historians—than by social scientists. Few among the latter have explicitly or elaborately theorized the concept of empire. In the early twenty-first century, however, there were some signs of a change in these patterns, especially amidst widespread and often heated debate over the idea of a new American “empire.”

The relative dearth of theoretical elaboration thus coexisted with a remarkable effervescence of controversy and (especially, perhaps, since the 1980s) with influences coming from numerous academic disciplines, milieus, and indeed theoretical traditions. Empire, its aftermaths, and
its enduring significance have not only been the concerns of historians and political or international relations analysts. In recent years, they have become major preoccupa-
tions among cultural and literary critics and theorists. In some other fields too—political theory, economics and development studies, anthropology, human geography, and more—they have generated a rapidly growing and often highly contentious literature. There has, however, been a relative lack, still, of interaction between political, economic, and strategic studies of global power on the one hand, and work by literary and cultural studies scholars interested in the cultures and discourses of imperialism on the other. These spheres of research have operated largely in an atmosphere of mutual indifference or even antagonism, and although here too a growing body of recent work seeks to close the gaps, they remain wide.

Diversity, imprecision, and ideological inflection have inevitably followed from that background. The terms empire and imperialism have at times been used to refer to all forms of relation between more powerful states or soci-
eties and less powerful ones. They have also, even beyond these loose boundaries, often been employed in academic discourse in a great range of vaguely allusive, metaphorical, or polemical ways. They have additionally been inter-
twined with several other, mostly newer but equally contentious words: especially colonialism, and latterly neo-
colonialism, globalization, and others. A great range of compound terms has also been thrown into the stew at different times and places: informal empire, subimperialism, cultural imperialism, internal colonialism, postcolonialism, and many more.

DEFINITIONS

More substantive attempts at definition have centered around the notion of an empire as a large political body that rules over territories outside its original borders. It has a central power or core territory—whose inhabitants usu-
ally continue to form the dominant ethnic or national group in the entire system—and an extensive periphery of dominated areas. In most cases, the periphery has been acquired by conquest. But in earlier imperial systems, expansion sometimes came about by such means as the intermarriage of ruling families from previously separate states. And in some modern instances, the ruling elites of the peripheral territory may have chosen willingly to be brought under the control of the imperial center. Some scholars have argued that empire necessarily involves political sovereignty or direct control by core over periph-
ers; but others, probably more, have used the term also for informal control, influence, or hegemony. A world, or parts of it, dominated by empires is often explicitly or implicitly contrasted to one of nation-states; especially in terms of a (usually implied) narrative of twentieth-century global history in which the former is seen as having been replaced by the latter, involving the extension of an origi-
nally European nation-state model across the globe. However, whilst some analysts have seen the concept of empire as distinct from or even the antithesis to that of the state, others identify it rather as a particular form of state.

Empires, then, are composite entities, formed out of previously separate units. Diversity—ethnic, national, cultural, often religious—is thus of their essence. But that cannot be a diversity of equals. If there is no relation of inequality and domination between core and periphery, then the system is not truly an empire but a federation or perhaps a commonwealth. Both the British Empire in its last stages and the post-Soviet Russian federation used the latter term for themselves, indicating the claim that they were no longer imperial systems but free associations of equals.

The relationship between the concepts of empire and imperialism on the one hand, and colony and colonialism on the other, have been particularly fraught with ambiguity. Early usages of the latter mainly associated it with the physical transfer of large settler populations to new places: often, but not always, associated with the political conquest of such places and with the settlers attaining a position of dominance over (or even exterminating) indigenous peoples. More recently, some scholars have distinguished between imperialism and colonialism by way of seeing the former as an attitude or policy advocating territorial expansion, whilst the latter is the practice of domination or overrule. Most often, however, the distinction drawn (albeit not always explicitly) is that colonialism is used to mean situations of direct control or the exercise of sovereignty by one people or country over another, whilst the concepts of empire and imperialism are more encompassing and embrace also less direct or formal forms of domination.

ETYMOLOGIES AND HISTORIES

The word empire comes from the Latin imperium, for which the closest modern English equivalent would perhaps be sovereignty, or simply rule. For the Romans, an emperor was originally a victorious general, later a supreme magistrate—though the military overtones of the title never disappeared. Imperium also came, both in the Roman era and later in Christian Europe—which derived so much of its political language and thought from Roman precedents—to have three further connotations. All these have continued to shape thinking about empire. First was size. Empire came to mean rule over extensive, far-flung territories, far beyond the original “homeland” of the rulers. Although some quite small entities have, historically, described themselves as empires, in most modern usages the term is reserved for very large political units.
Second was the notion of absolute sovereignty, acknowledging no overlord or rival claimant to power. When Henry VIII (1491–1547) of England had his realm proclaimed an “empire” in the 1530s, the aim was to assert that he owed no allegiance to, and would tolerate no interference from, either the papacy or any secular power. Third was an aspiration to universality. Christian (and, in a distinct but related idiom, Islamic) empire was in principle boundless, as the Roman imperium to which it was partial heir had claimed to be.

An empire is therefore, by a minimalist or semiconsensual definition, a large, composite, multiethnic or multinational political unit, usually created by conquest, and divided between a dominant center and subordinate, sometimes far distant, peripheries. Core and periphery are usually geographically separate, clearly bounded places. In modern seaborne empires, they might indeed be thousands of miles apart. In other cases, though, the geographical lines between them might be blurred. They might even inhabit the same physical spaces: ideas like internal colonialism were developed to try and explain such situations.

Imperialism is generally used to mean the actions and attitudes that create or uphold such big political units—but also, often, less direct kinds of control or domination by one people or country over others. Terms like cultural or economic imperialism are often used to describe some of these less formal sorts of domination: but such labels are invariably contentious. So too is the concept of informal empire, which has nonetheless been very influential and widely used to describe varied forms of dominance without formal sovereignty or direct political control, as with Britain’s nineteenth-century hegemony in Chile and Iran, or the more recent role of the United States in much of Central America.

Even formal empire, however, typically involved some combination of direct and indirect rule. The central power has ultimate sovereignty, and exercises some direct control, especially over military force and money-raising powers, in all parts of its domain. But there has usually been some kind of “colonial” or “provincial” government in each of the empire’s major parts, with subordinate but not insignificant devolved powers of its own. These authorities may be headed by men sent out from the dominant center. But their leaders, and certainly their more junior administrators or enforcers, may also be drawn from the ranks (usually from the preconquest ruling orders) of the dominated people. In many empires, ancient and modern, there was a general tendency over time for imperial rulers to devolve ever more power to such groups. In the long run, of course, this might lead to the gradual breakup of the empire itself. But many historians argue that the key to understanding empire lies in the bargains struck between the imperial center and local “collaborators.” No empire could last for long if it depended entirely on naked power exerted from the center outward. Local intermediaries might enjoy much autonomy within their own spheres, and command considerable wealth, power, and status, in return for delivering their people’s obedience, financial tribute, and military services to the center. This is so also in a different sense where (unlike the British or indeed any modern European-imperial case) the ruling elites of empires were themselves ethnically diverse, as with the later Roman Empire or the Ottoman Empire.

The emphasis on intermediaries, collaborators, gains, and decentralization should not be pushed too far. Empire was also often, indeed perhaps typically, established and maintained by violence. Sometimes extreme violence: some historians say that most episodes of genocide and mass murder in world history have been associated with empire building. This includes the Nazi Holocaust, which is increasingly analyzed as part of an “empire-building” project. More generally, the idea of empire in modern history has also usually been associated with European, white rule over non-Europeans, with “racial” hierarchies and racist beliefs. Some analysts, again, build this association into their very definitions of empire.

One other aspect of debates over the historical salience and transformative force of European (especially British) expansion has been especially vigorous. Should colonial rule be viewed primarily in terms of modernization or of archaism? The notion of colonial modernity—even colonialism as modernity—has been widely invoked, especially among recent cultural historians of empire. The idea of colonialism as a modernizing, state-building, centralizing, developmentalist, and secularizing force has been deployed too by those urging a positive appraisal both of the British imperial record and of American “empire” today. Yet on the other hand, some historians stress instead the traditionalist and even archaizing features of British imperial ideology.

VARIATIONS AND SIMILARITIES

Empires have, rather obviously, taken a wide variety of forms across history. Even where empires, especially imperial ideologies, display close family resemblances, this has sometimes reflected conscious imitation more than structural congruity. Some scholars, indeed, urge a definitive abandonment of the singular term empire—which tends, even when its users are stressing and tracing differences, to imply that these are variations on a single essence—and propose a mandatory pluralization of the terms empires and imperialisms. Yet most see, at least, broad similarities as well as some fundamental subcategories among empires. Perhaps the most basic and important of the lat-
ter is the division between those that grew by expansion overland, extending directly outward from original frontiers, and those that were created by sea power, spanning the oceans and even the entire globe. The first, land-based form of empire is by far the older and the more historically ubiquitous. Land empires were created by Asians, Africans, and pre-Columbian Americans as well as Europeans. The second, mainly European form, however, has been the most powerful and dynamic in the modern world—roughly the last five hundred years. It in turn is often analyzed as having two main forms: settlement and nonsettlement colonies. The former category includes those places where large numbers of Europeans moved and remained. In some—notably, most of the Americas and Australasia—they became the vast majority. In others, like Algeria, South Africa, and more precariously in Kenya or Zimbabwe, European settlers became dominant minorities. The nonsettlement colonies, embracing most of Africa and South and Southeast Asia, were considerably more numerous and far more disparate in nature.

The character and continuing consequences of empire thus remain intensely contentious. At the peak of their strength in the first half of the twentieth century, European colonial powers, plus their offshoot the United States, ruled well over 80 percent of the world’s land and effectively controlled all the oceans too. That direct physical dominance mainly came to an end, with remarkable rapidity, between the end of World War II (1939–1945) and the 1960s. But its effects remain indubitably important, both for formerly colonized and for ex-imperial peoples. And a wide range of critics—especially socialists and third world nationalists, but also such disparate currents as contemporary antiglobalization protesters and militant Islamists—argue that the twenty-first-century world witnesses not just the continuing consequences of old-style European colonialism, but a new kind of global empire headed by the United States and its allies. For some such critics, indeed, empire is now effectively a simple synonym for American foreign policy. In a slightly less polemical vein, scholarly argument has proliferated over the existence, character, and importance of continuities or parallels between the formal colonialism of the nineteenth and twentieth centuries and the global politics of the twenty-first.

EMPIRICISM

Empiricism can be traced back to Aristotle’s dictum, “there is nothing in the intellect that is not first in the senses,” although Aristotle himself is not usually regarded as an empiricist in the modern sense. The theoretical foundations of modern philosophical empiricism are found in the works of John Locke, George Berkeley, and David Hume, and in the nineteenth-century philosopher William James. These philosophers inquired about the limits and scope of the human mind, and argued that experience itself is the primary source of all knowledge. Empiricism is thus a theory of knowledge that highlights the importance of experience. The term experience can be defined minimally, as in terms of the senses, or expanded to include all forms of consciousness.

Locke’s project in his Essay Concerning Human Understanding (1690) was to set out “to enquire into the origin, certainty, and extent of human knowledge” (Locke 1975, p. 43). Locke argued that knowledge is restricted to ideas generated by objects that one experiences through the senses (ideas of sensation) or by reflection upon our mental operations on those ideas (ideas of reflection). In this complex sense, knowledge and human understanding
in general (including unscientific beliefs such as justice) originate in experience, as the origin of all ideas is in experience, which involves two logical levels, sensation and reflection. Each person's mind can be thought of as initially a blank tablet (tabula rasa) first written upon by the sensations of experience (ideas of sensation), which can then be manipulated in various ways, the ideas of which—the ideas of reflection—being the second level of experience.

Berkeley argued in both Principles (1710) and Dialogues (1713) against the actual existence of matter, and claimed in his dictum "to be is to be perceived" (or to perceive). This means that objects can never be understood independently of their ideas since, for Berkeley, the object and sensation are the same thing. Berkeley maintained that there are only ideas and minds, or the location where ideas occur. Thus a thing is understood as the sum of perceived qualities. Although for Berkeley it is impossible to think of anything except as it related to the mind, both Berkeley and Locke believed that all knowledge about the existence of things and the reality of matter depends on visual and sensory experience.

In his work Enquiry Concerning Human Understanding (1784), Hume claimed that human senses allow people to perceive, and these perceptions (made up of impressions and ideas) are the contents of the mind. The original thought itself, according to Hume, is an impression, and an idea is only a copy of an impression. The difference between the two is their vividness, for when one reflects upon these impressions one has ideas of them. Hume’s work does not ground impressions to a material world, and argues instead that impressions are internal subjective states that do not provide evidence of an external reality.

In his metaphysics, James wrote in a tradition that focuses on the process of consciousness based in experience—a “process metaphysics.” For James, humans have a continuous development of thought that is based in interpretations of the experiences themselves. In this way, human consciousness consists of experienced relations (a “stream of thought”), which are themselves experienced (affectively and effectively), as one both transforms and is transformed by these experiences. Indeed, James’s radical empiricism is pluralistic in that it allows for different points of view—different “givennesses”—of reality. Because James allowed for individual perspectives of experience, it follows that one’s epistemologies themselves are informed by one’s experiences. Absolute unity of reality, for James, is “ever not quite,” as “fact” is based on experience, and the multiple experiences of experience itself. Thus there is no objective truth, as Jamesian truth is experientially cognized at the level of subjective/individual perception.

The empirical tradition runs counter to rationalist philosophy, which poses that knowledge can be derived through the exercise of reason alone, and in terms of a person’s rational power. All of the aforementioned philosophers wrote in a tradition that opposes the rationalist view, represented most notably by the French mathematician and philosopher René Descartes, that humans enter the world with innate ideas built into the mind itself. Instead, these philosophers argue that persons must rely on experience itself to inform knowledge claims.

RESEARCH AND EMPIRICAL METHODS

Within the social sciences, empiricism describes research methods that depend on the collection of facts and observations, some of which require verification, counting, and measuring. Although a researcher may use empirical methods, it does not follow that he or she is a philosophical empiricist, and does not make one an empiricist per se. There are thus many forms of empirical research methods.

Auguste Comte, a sociologist and philosopher, held that knowledge of the world arises from observation, and conceived of positivism as a method of study based on the strict use of the scientific method. He asserted that authentic knowledge (or all true knowledge) is scientific knowledge that is objective, predictable, and has logical structures. Logical positivism (or logical/rational empiricism) combines positivism with a verifiability criterion for meaningfulness. For logical positivists, all knowledge should be based on logical inference, justification, and verifiability through experience or observation. Meaningful statements fall into two categories for the logical positivist, a priori analytic knowledge (necessary truths that are knowable prior to experience; for example, all circles are round) and a posteriori synthetic knowledge (or contingent knowledge that is verified by sensory experience; for example, it is raining outside). Quantitative methodology is a kind of scientific empiricism and refers to the compilation and analysis of numerical data, which for the social scientist is empirical in nature since it can be tested and verified (validated or falsified) by empirical observation. Moreover, quantitative methodology is positivistic since it relies on scientific and systematic observation and experiment, and can be thought of as the scientific approach to the study of sociocultural life.

Nonetheless, although social scientists do not ask underlying metaphysical questions about the actual existence of objects, they are indeed concerned with the experience of social objects and phenomena. For example, the first professor of sociology, Émile Durkheim, in his book The Rules of Sociological Method (1938), enshrined this
idea with his conceptualization of a “social fact,” which is as objective as facts are in the natural sciences.

For Thomas Kuhn, empirical methods are capable of elucidating and eradicating problems within paradigms during periods of “normal science.” Interestingly, Kuhn shows how this “science” is reflective of one’s theoretical connectedness to a specific paradigm itself, and is not the reflection of any truth-claims to knowledge.

Social constructivism is a philosophical theory of knowledge that states that knowledge itself is contingent upon social experience, context, convention, and human perception. Some examples of socially constructed knowledge are gender (feminine and masculine), sexuality, and racial categories. This theory of knowledge does not necessarily reflect any external “transcendent” metaphysical reality, and is instead based on a socially constructed reality as opposed to an ontological reality. However, the notion of experience is still important for a constructivist, as experiences between and among individuals differs within and outside of varying contexts, thereby allowing for different “realities,” some of which are based in oppression (for example, women, minorities, and homosexuals).

Empirical methods have been used to study race, gender, sexuality, and religion, among a plethora of other social phenomena such as crime, deviance, attitudes, and beliefs.

Considering race, there has been much research done in social science regarding migration, connections with class, connections to skin color, social surveys of self-image and self-regard among ethnic minorities, and measuring prejudice in terms of scales of social and ethnic “distance.” Additional quantitative studies concerning race have focused on social inequality, institutional racism, patterns of interaction and segregation, genocide, social standing, poverty, and assimilation of dominant culture patterns.

Gender has been studied in the social sciences through the analysis of images of women in media and culture. These empirical studies of symbols and images range from studies of archaeological statues of goddesses to contemporary studies of how women are portrayed in film or advertisements. Discrepancies in gender stratification and sexism can be analyzed from a quantitative approach, as can the important issue of violence against women. Additionally, empirical studies of gender also inform analyses of family relations, employment patterns, and distribution of wealth, education trends, and politics.

Using empirical methods to study sexuality, social scientists focus on topics such as sexual orientation, contraception, prostitution, gender identity, and attraction. Additional research can also be found on teen pregnancy, fertility, pornography, activist movements, sexual violence, sex education, and queer studies. One of the most important works in this area is The Archaeology of Knowledge (1972) by Michel Foucault.

Religion has also been analyzed empirically in terms of socioeconomic status, the family, marriage patterns, social class, family violence, cohabitation, political affiliation, church attendance, opinions about religious matters, as well as feelings, beliefs, and behaviors pertaining to religion as measured by social surveys. This is especially evident in the work of Rodney Stark, but began as early as 1904 in Max Weber’s seminal work The Protestant Ethic and the Spirit of Capitalism.

Louis Althusser critiqued empiricism as a methodological stance and argued against the empirical process of knowledge, claiming that theoretical discourse is a “production,” making empiricism itself ideological and dogmatic, and therefore not scientific. According to Althusser, “facts” of theoretical discourse are tied to theoretical practice, making knowledge itself a form of discourse.

EMPLOYMENT

Employment measures the number of employees in a country, region, or sector. Employees are generally defined as persons on payrolls, that is people who are compensated for the work they perform. Depending on the particular definition, this may or may not include self-employed people, also called proprietors, who work for themselves. Along with unemployment, employment (including proprietors) constitutes the labor force. Including people working without pay, for example housewives, volunteers, and sometimes armed forces, one obtains the workforce. Finally, all the population capable of working constitutes the manpower.

MEASUREMENT

Measurement of employment is quite diverse across countries, which makes cross-country comparisons difficult. There can be variations in definitions, coverage, data collection methods, information sources, and estimation methods. For example, the United States publishes employment data from two different sources. The National Current Employment Statistics (the so-called establishment survey) from the Bureau of Labor Statistics does not cover agriculture, hunting, forestry, fishing, the armed forces, and private household services. Sick leaves, paid holidays, and employees on strike (but not the whole period) are counted. The Current Population survey (the so-called household survey), also from the Bureau of Labor Statistics, covers the civilian population sixteen years of age and older in all sectors, except armed forces. It counts as employees those who “(1) did any work at all as paid employees, worked in their own business or profession or on their own farm, or worked fifteen hours or more as unpaid workers in a family-operated enterprise; and (2) all those who did not work but had jobs or businesses from which they were temporarily absent due to illness, bad weather, vacation, childcare problems, labor dispute, maternity or paternity leave, or other family or personal obligations, whether or not they were paid by their employers for the time off and whether or not they were seeking other jobs.”

Intertemporal comparisons of employment are more reliable, although they can also be subject to changes in definition or coverage. For example, the introduction of child labor laws and mandatory schooling has increased the minimum age considered for employment statistics.

Most frequently, employment data is based on surveys, sometimes complemented by various techniques to increase precision or interpolate between data points. Employment may also be inferred from data provided by trade unions, trade associations, social security administration, or other government agencies.

LONG-TERM TRENDS

The sectoral composition of employment has changed considerably in human history. Because under a strict definition of employment self-employment is not considered, a labor market with an explicit exchange of work for payment evolved sometime during the last millennium, after both the introduction of money and the existence of surplus labor in agriculture. This surplus labor made the specialization of tasks possible, in particular for various manufacturing trades. Once production expands beyond the abilities of a family, external labor needs to be hired and a labor market is born. The extent of this labor market has been very limited, however, for a long time, in particular as slavery and servitude are not considered to be employment. It is the Industrial Revolution that allowed a significant take-off of employment, through the creation of factories where proprietors constituted a very small minority of workers and the preceding second agricultural revolution that created significant excess labor on farms. Even in the twenty-first century, employment measures typically exclude agriculture, as the latter is still considered to be largely the domain of proprietors.

In all industrialized economies, employment has thereafter gradually shifted toward services, which now typically constitute a larger share of employment than manufacturing. Employment also requires better skilled workers and has an ever-increasing share of female employees. Better skills are required to operate or monitor more sophisticated machinery, to provide more elaborate services, or to use computers. The increased female involvement in employment can be traced back to two main factors: (1) the emancipation of women breaking the traditional role of the housewife, along the decline of the wage gap with men; and (2) significant improvements in technology used in housekeeping (such as washing machines and vacuum cleaners) that made it possible to pursue paid work outside of the house.

One source of considerable controversy is whether technological progress has a positive impact on employment or not. As was the case with the Industrial Revolution, rapid technological progress can lead to a massive sectoral reallocation of employment, which does not necessarily mean a reduction in employment. For example, while the introduction of the steam engine rendered horses obsolete for most of their original tasks, such obsolescence is more difficult to reach for humans, given...
their versatility and their ability to adapt. But this still happens, in particular for workers close to retirement. On a more microeconomic level, technological progress simultaneously destroys and creates jobs. In this context, several kinds of technological progress can be identified, depending on how they alter the aggregate capital/labor ratio in the production process; it is labor augmenting if progress reduces this ratio, labor saving otherwise, or non-biased if it leaves the ratio unchanged. Over the long term, the capital/labor ratio has increased steadily, both through capital accumulation and through a reduction in the work hours. The labor income share, however, does not exhibit any particular trend and there is no conclusive relationship between the unemployment rate and various measures of the growth rate.

The last two decades of the twentieth century witnessed another important development: globalization. The wage pressure from developing or emerging countries influenced employment, in particular for low skill jobs in manufacturing, but also increasingly for higher skilled positions in services. There is, however, no agreement among scholars whether this impact has been significant at the macroeconomic level (it certainly was in some sectors of the economy), and whether it has been negative at all. Indeed, while some jobs were “exported,” the availability of intermediate goods at lower prices increased the productivity of some sectors that then expanded. It is, however, clear that lower skilled workers face reduced employment opportunities, a phenomenon that started even before globalization accelerated.

INFORMAL EMPLOYMENT
One important distinction in the labor market is between formal and informal employment. There are many definitions of informal employment, the most common being employment that escapes taxation and regulation, and thus is not protected by the government: Various social programs do not apply to informal workers, such as unemployment insurance, social security, some labor laws (in particular the enforcement of contracts), or invalidity and accident coverage by the government. Informal employment is much more widespread in developing economies, where social programs are less common and tax authorities have less control. Yet informal employment is still present in developing economies; for instance in 2000 Friedrich Schneider and Dominik H. Enste estimated informal employment to reach around 10 percent of employment in the United States, higher in other countries, typically those with higher labor income tax rates or inefficient taxation.

As the informal sector escapes regulation, it is generally viewed that it should be limited. In many cases, however, it is a response to overregulation or corruption. Workers may migrate between formal and informal sectors as opportunities arise, the informal sector often being regarded as a stepping-stone in which skills are learned before being hired in the formal sector. Accordingly, wages are lower in the informal sector. Informal firms are typically family based and small, have low productivity, and have very low capital intensity. Workers are hired on a casual basis on arrangements of short duration.

CHILD LABOR
One aspect of labor markets, especially in developing economies, is child labor. One commonly defines child labor as the participation of school-aged children on a regular basis in the labor force in order to earn a living for themselves (street children) or to supplement household income. The International Labour Organization (ILO) divides child labor into three categories: (1) labor that is performed by a child who is under the minimum age specified for that kind of work defined by national legislation, and that is likely to impede the child’s education and full development; (2) labor that jeopardizes the physical, mental, or moral well-being of a child, either because of its nature or because of the conditions in which it is carried out, known as hazardous work; (3) the unconditional worst forms of child labor, which are internationally defined as slavery, trafficking, debt bondage and other forms of forced labor, forced recruitment of children for use in armed conflict, prostitution and pornography, and illicit activities.

The national laws of most industrialized countries abolished child labor by the end of the nineteenth century. However, in 2000 Douglas Kruse and Douglas Mahony estimated that several hundred thousand children work illegally in the United States. Worldwide, the ILO estimated (with considerable uncertainty) that 218 million, or 16 percent of children aged five to eleven were working in 2004, 126 million in hazardous work.

The ILO pushes very hard to eliminate child labor where it is the most prevalent, in developing countries. While the strategy is generally to have governments ratify conventions and implement child labor laws, those methods are often insufficient. As long as schools are sufficiently effective in providing education (not a given), parents are very aware of the high returns to education. Yet they often send their children to work because their contribution is needed to sustain household income. As the children do not get an education, their income as adults will be too low to allow their offspring to go to school. Breaking these vicious circles is the key to eliminating child labor, as the implementation of child labor laws in North America or Europe has shown.
**BUSINESS CYCLES**

All economies are subject to fluctuations and one important aspect of business cycles is the systematic changes in employment. Indeed, in most cycles and most economies, employment and gross domestic product (GDP) evolve in tune: GDP and the total number of hours worked typically reach their peaks or troughs at the same time and fluctuate about as much. Employment, however, tends to fluctuate (in percentage terms) less than GDP and tends to lag the movements of GDP by a few months. While these regularities can be observed across all economies, there are some striking differences. For example, fluctuations in total hours worked in some economies tend to happen on the intensive margin (hours per worker) rather than on the extensive margin (employment). In other words, there are more changes in overtime or undertime than hiring and firing. This is true for several European economies, but not for the United States, primarily because of the influence of labor laws, labor market traditions, and unions.

There are also clear patterns through the business cycles in terms of hiring and firing. Plant level studies have revealed that most of the fluctuations in employment can be explained by job destructions: These are high in a recession and low in booms. Job creations are, however, much more stable through the business cycle. It is also generally observed that employment fluctuates significantly more for less educated workers.

**POLICY**

Many government policies affect employment, and it is impossible to review them all. One can distinguish between those that have an impact on the average level of employment, and those that try to mitigate employment fluctuations. Whenever policy is involved, some welfare criterion needs to be established if one is to determine whether policies are good or bad. In this respect, psychologists consider that it is good for people to be employed, as this improves their self-esteem. Sociologists would consider the negative impact on one’s standing in society due to unemployment. Employment of women is considered to be a necessary part of their empowerment. Economists consider the fact that people would not necessarily want to work: They appreciate leisure more than work, and one symptom of this is that they are paid to work, instead of paying for this privilege. However, employment is a way to obtain the income necessary for consumption and savings. There are also various frictions on the labor market, such as the transaction costs and the difficult matching process between vacancies and unemployed workers, which make full employment unattainable. Thus, high employment is preferable, but not at any cost. However, child employment should be reduced to a minimum. Also, given that households generally do not like fluctuations in income, as they imply fluctuations in consumption, policies that stabilize employment are considered preferable, as long as they do not reduce average employment too much.

Employment is influenced indirectly but sometimes significantly by various policies, such as provisions of the tax code. For example, high or increasing marginal tax rates are known to discourage the participation of spouses on the labor market. The so-called marriage penalty in some tax codes—whereby the incomes of two spouses are added to determine the tax rate instead of considering the incomes separately—has the same effect.

Employment policy is enacted to improve working conditions or facilitate the employment opportunities of some workers. Those categorized as active employment policies include job placement agencies, labor market training, and subsidized employment. Passive policies include unemployment insurance and early retirement programs. Scholars, including David Grubb and John Martin, debate the effectiveness of these policies, in particular in light of their costs, which lead to an indirect discouragement of employment through higher tax rates. Or a generous unemployment insurance system may also encourage unemployed workers to reject job offers in the search of better matches, thereby lowering employment and increasing the costs to fill vacancies.

Labor laws are put in place to prevent abuses and to organize the labor market. They may also have perverse effects on employment. For example, laws putting restrictions or making it more difficult to lay off workers may prevent them from being hired in the first place, especially in sectors where employment would exhibit stronger fluctuations or where workers may have private information about their qualifications. Finally, generous minimum wage laws are generally thought to have adverse effects on employment, as some employers would not open vacancies if wages have to be higher. While there is controversy in the literature about this, the employment effects of minimum wages may simply be small.

This discussion may give the impression that any intervention in the labor market has harmful effects. Labor markets have particular characteristics that make government intervention necessary, but without excess as negative indirect effects may outweigh positive direct effects. The right to unionize is enforced to counter the monopoly power that employers have in a very fragmented labor market. But too much union power leads to excessive negotiation power for employees, and then to high wages that prevent the hiring of additional workers.

Stabilization of employment through the business cycle is generally viewed through the lens of avoiding fluctuations in unemployment. Monetary policy has a long
tradition of playing with the trade-off between (expected) inflation and the unemployment rate, the so-called Phillips curve. Monetary policy has, however, shifted from an active stance in the Keynesian tradition to a more passive stance seeking to stabilize inflation at rather low levels. It has been recognized that monetary policy can do little about (un)employment due to large delays and uncertainty about the impacts.

Fiscal policy has and is still being used for stabilization purposes in some countries, but again the tendency is toward a hands-off approach. Where it is applied, it is through public works programs, temporary tax breaks directed to firms to encourage hiring or to prevent layoffs, or income tax breaks to encourage consumption and economic activity in general. Again, such policies are not generally viewed to be advisable as delays in implementation or effectiveness are typically longer than a recession. However, they have a certain political appeal.

EMPLOYMENT, WHITE COLLAR

The concept of “white-collar” employment has been deeply embedded in ordinary language since the early twentieth century, denoting those who work in offices and apart from the dirtier “blue-collar” world of manual or physical labor. Historically, when the large majority of work was of the latter type and large corporations were just beginning to expand the ranks of office workers, the “white collar” symbolized new opportunities for upward mobility. Over time, however, an increasing economic complexity has created new categories and blurred the original lines, so that the term has gradually lost usefulness as an analytic concept. In 2006, the U.S. Bureau of Labor Statistics declared that “the white collar and blue collar series are no longer useful categories and will be discontinued in 2007” in compiling its Employment Cost Index data.

For most of the twentieth century, white-collar employees were united by some perquisites that distinguished them in practice from blue-collar workers. For one thing, they were treated as nonproduction overhead and were, therefore, protected to a considerable extent from efforts to control production costs. White-collar workers were also paid salaries, rather than wages, and they generally enjoyed a high degree of job security. When layoffs were needed in production downturns, it was generally those on the factory floor who were let go.

White-collar employment grew substantially during the twentieth century, primarily at the expense of farm and manual workers. According to the Bureau of the Census data, white-collar workers increased from 17.6 percent of total employment in 1900 to 59.9 percent in
2002 (analyzed and reported by the Department for Professional Employees 2003, p. 5). But this general statement obscures many crucial distinctions.

CONCEPTUAL AND DEFINITIONAL INCONSISTENCIES

Even in its early usage, “white-collar” was less than coherent conceptually, covering at least three radically different types of workers. Clerical occupations were largely female, low-status, and low-wage; managers and professionals, on the other hand, were largely male and high in status and pay. A third piece of the white-collar picture was comprised of professionals, who themselves changed dramatically in status from largely independent workers in the early part of the twentieth century to primarily working for corporations at the end. There was practically no mobility among these three categories, and their wages varied widely. As unionization advanced in mid-century, for example, clerical workers were paid less than blue-collar workers, but managers and professionals were paid more.

This conceptual inconsistency has grown even more marked and complex with the growth of services and knowledge work. Beneath the seemingly precise counts in various surveys lie important dissimilarities in definitions. For example, most analysts believe there has been a significant growth in service work since the early 1900s, though they disagree on how to define it. Service work is, in some sense, different from the production of “things,” which defines blue-collar work, but service workers are not necessarily white-collar. Building maintenance, for example, is certainly “manual” in nature, but it is not considered “office work.”

The Census data calculate that about 14 percent of the U.S. workforce is in services, though an independent analysis by Marc Uri Porat in 1977 put the percentage at 30 percent, without counting “information workers.” This is just one indication of the inconsistencies in the field.

Many analysts argue that a large economic discontinuity has occurred with the growth of “knowledge work” as a key part of the economy. There have been many attempts to count knowledge workers, starting with Fritz Machlup’s pioneering 1962 study. The estimates continue to vary rather widely, depending on what assumptions are made, but it is clear that adding this category produces a radically different view from that based on “collar.” For instance, a recent study by Edward Wolff estimates that 15 percent of the workforce in 2000 were knowledge workers (producing new knowledge), 44 percent were data workers, 14 percent were service workers, and 24 percent were goods producers.

KEY THEORETICAL TREATMENTS

Theoretical treatments of white-collar work have struggled to identify consistent patterns, hampered in part by the diversity of definitions. One of the most famous, C. Wright Mills’s *White Collar*, focused on administrative staff in large corporations in the late 1940s. Mills found that these workers were caught in a psychology of "pres-
tige striving,” with no independent basis of identity, and he predicted they would remain a weak and confused force socially and politically. Marxist treatments, such as that of Nicos Poulantzas, have also often suggested that white-collar workers lack a clear class identity and can potentially be drawn to either side of the primary class divide. Some, however, have identified distinct and independent forms of white-collar consciousness: Barbara and John Ehrenreich sketched a new “professional-managerial class”; Robert Merton sketched a “bureaucratic personality” based on “strong sentiments which entail devotion to one’s duties, a keen sense of the limitations of one’s authority and competence, and methodical performance of routine activities”; and Olivier Zunz suggests that middle managers and professionals in America have adopted a distinctive “rational” ethic. Scholars of Nazi Germany, meanwhile, have suggested that white-collar workers provided a reactionary base for Hitler’s rise (Kocka 1980).

RECENT DEVELOPMENTS: PRODUCTIVITY, UNIONIZATION, AND SECURITY

The growth of white-collar occupations has posed a new problem for economic analysts: The productivity of these workers is very hard to measure. There was deep concern in the 1980s about the slowdown in productivity growth, especially in the white-collar and technical ranks. However, this concern was accompanied by a debate about whether the slowdown was real or merely an artifact of measurement failure. Steven Roach, the chief economist at the investment bank Morgan Stanley, suggests that “it may well be that white-collar productivity improvements are simply much harder to come by than blue-collar ones” (Roach 1998).

A good deal of attention has been paid to the potential for unionization of this sector. Many scholars and practitioners have assumed that white-collar workers are resistant to unionism because of their identification with management, and for the first half of the twentieth century their unionization rate was apparently very low. In some countries, such as Sweden, however, white-collar employees (including managers) have formed strong unions of their own; and since the 1950s there has been a substantial growth of white-collar unionism in the United States as well—especially among professionals such as teachers and nurses.

Among the most dramatic and important developments since the 1970s has been the breaking of the widely recognized “psychological contract” of loyalty and job security between corporations and their white-collar forces. Beginning with the 1974 recession, and accelerating greatly in the 1980s, corporate managers began to explicitly consider middle managers as a focus of potential cost saving. This was in part a rational response to the growing weight of white-collar labor costs, but it was also linked to a broader ideological shift that downplayed the value of stability and security and emphasized instead values of entrepreneurship and individual risk taking. Though economists have found only modest evidence of real changes in white-collar employment tenures, there has been strong documentation (e.g., Leinberger & Tucker 1991, Heckscher 1995, Cappelli 1999, and Newman 1998) of a sharp shift in “mindset” among managers and technical staffs. There is now a mix of fear and anger at the loss of security and enthusiasm for new opportunities, though this mindset has not yet settled into a consistent attitude toward the widespread changes these workers are facing.

ENDOGENOUS PREFERENCES

Preferences are endogenous when they are determined by, and may change as a result of, other factors. Preference endogeneity appears as an issue, for example, in explaining behavior driven by altruistic, reciprocal, or envious preferences, conformity to social norms, and the effect of persuasive advertising. Although it may appear obvious to noneconomists that preferences change and that economists should account for them, standard neoclassical economic theory takes preferences as exogenous. There is no doubt that apparent evidence for unstable preferences can be explained by suitable ad hoc assumptions embedded into stable, and exogenous, utility functions. Nevertheless, it is questionable whether ad hoc assumptions can be held as serious competitors to more psychologically realistic views of preferences as subject to change.

But endogenous preferences are unattractive to many economists for understandable reasons: (1) neoclassical economic theory assumes utility maximization of a stable utility function, and the risk of allowing the utility function to change is to be able to explain everything by suitable tinkering, and thus explain nothing; (2) endogenous preferences typically imply a loss of parsimony in the economic model, a loss accepted as essential by some (e.g., Bowles 1998) but not by most; and (3) endogenous preferences also make welfare analysis more difficult since normally welfare is measured in terms of utility, and if the utility function changes as a result of a policy change, the metric on the basis of which welfare is measured also changes. A partial solution to problem three is to show that a policy change is better, or worse, according to the preferences held both before and after the policy change. Problems one and two might be answered by good theory and evidence combined.

There is clear evidence for the instability and endogeneity of preferences in specific setups. For example, when decision makers repeatedly face a new situation, such as a market in the experimental laboratory, a learning process takes place where agents shape their preferences in interaction with the market setup. Gary Becker and Kevin Murphy (1993) reviewed the ten U.S. companies with the largest ratio of advertising expenditures to sales, and noted that many of the products the companies produced—such as chewing gum, beer, or cola—conveyed no or very little information. Among others, Samuel Bowles (1998) and Daniel Zizzo (2003) reviewed a variety of evidence on the endogeneity of altruistic, reciprocal, and envious preferences.

The status of theories of endogenous preferences is, however, less satisfactory. Institutional economics accounts, such as Wilfred Dolfsma (2002), are interesting but generic. Behavioral economics models do little more than arbitrarily postulate certain endogenous relationships. Evolutionary game-theoretical models of altruistic, reciprocal, and envious preferences abound (e.g., Bowles 1998), but they typically involve zero-rational agents (where a modicum of rationality could make a difference) and are liable to criticism as evolutionary just-so stories. Artificial-intelligence approaches (based on neural network or hybrid modeling) may help and may be testable against data, but have so far been mostly neglected.

Energy

**ENDOGENOUS VARIABLES**

SEE Variables, Predetermined.

**ENERGY**

The broadest definition of energy is the ability to do work. Human societies tap into various forms of energy, including chemical energy in biomass, natural gas, coal, and petroleum; nuclear energy in uranium; gravitational energy captured in hydroelectric plants; wind energy; and solar energy. Energy is usually measured in British thermal units (BTUs). A BTU is defined as the amount of heat energy that will raise the temperature of one pound of water by one degree Fahrenheit. In 2005 the world economy obtained about 40 percent of its nonsolar energy from petroleum, about 23 percent each from natural gas and coal, 8 percent total from hydroelectric, wind, and thermal sources, and about 6 percent from nuclear. Most of this energy is used in the industrialized world, although the most rapid growth in energy use is occurring in the industrializing world, especially China. The largest use of energy by far is for industrial production and transportation.

Energy has been a crucial factor in human cultural evolution. The evolution of increasingly complex human societies was driven by the capacity to harness energy. Harnessing energy may have also played a key role in our biological evolution. The large human brain, unique even among primates, has enormous energy requirements. The human brain represents about 2.5 percent of body weight and accounts for about 22 percent of resting metabolic needs. This large energy requirement was met by a much higher proportion of protein in the diet of early humans and the use of fire to predigest meat. The use of fire played a role in the anatomical development of our species—larger brains and shorter guts—and paved the way for further advances in technological and cultural evolution.

Beginning about 10,000 years ago, early agricultural technology harnessed flows of solar energy in the forms of animal-muscle power, water, and wind. With the widespread use of wood for fuel, humans began to tap into stocks of solar energy rather than flows. The use of stocks of energy made it possible to capture ever larger amounts of energy per capita with smaller amounts of effort. Wood, wind, and water power fueled the industrial revolution, which began in the early eighteenth century. In the nineteenth century, ancient solar energy, fossil hydrocarbons in the form of coal, rapidly became the fuel of choice. During the twentieth century, petroleum and natural gas replaced coal as the dominant fuel. Each step in the history of energy use has been characterized by a dominant fuel type that is increasingly flexible and substitutable.

Since our industrial economy depends so heavily on fossil fuels, an obvious question is, “Are we running out of it?” Most economists answer this question with an emphatic “No!” As energy becomes scarce, its price will increase, calling forth substitutes, increasing conservation efforts, and encouraging more exploration for new supplies. Economists point out that past warnings of impending shortages have proved to be greatly exaggerated. Critics of the economic argument counter that the inverse relationship between energy supply and energy demand may be trivially true, but this does not mean that the increasing scarcity of an essential resource like petroleum can be easily accommodated. The economic argument also ignores the geopolitical consequences of the waning of the petroleum age.

A useful supplement to the price-based analysis of economists is the concept of energy return on investment (EROI). This is a measure of how many units of energy can be obtained from a unit of energy invested. If the EROI is less than one, it makes no sense to tap that energy source, no matter how high the price.

Although the world uses many types of energy, none of them have the flexibility and high EROI of petroleum. Of paramount concern is when world petroleum production will peak and start to decline. Most predictions of when worldwide oil production will peak are based on variations of a model developed by the geophysicist M. King Hubbert in the 1950s. He created a mathematical model of the pattern of petroleum exhaustion assuming that the total amount of petroleum extracted over time would follow a bell-shaped pattern called a logistic curve. Past experience for individual oil fields shows that once peak production is reached, production tends to fall quite rapidly. A number of petroleum experts argue that technological advances in the past decade or so have extended the peak of the Hubbert curve for specific oil fields, but this has made exhaustion more rapid after the peak occurs. Since oil is limited, policies promoting technology to make more energy available today mean that less will be there in the future.
Estimates of when world oil production will peak run from 2005 (production has already peaked) to 2030, with most predictions clustering around the years 2010–2012. Predicted consequences of declining oil production range from catastrophic scenarios as agricultural and industrial outputs plummet, to relatively mild scenarios as the world’s economies endure inflation and temporary economic hardships to adjust, to the rosy scenarios of free-market fundamentalists who claim that markets will quickly call forth substitutes and conservation that overcome the scarcity of any particular fuel type.

It is impossible to predict how the world’s economies will adjust to the end of the fossil-fuel age. So far energy policies in the developed and developing worlds have shown little concern for the limited amount of fossil fuels. What happens in the future depends on how much developing economies (especially China) grow and how energy-dependent they become. Also of concern is how the rest of the world will react to the growing concentration of petroleum reserves in politically volatile areas and the increasingly ominous effects of global climate change.

ENERGY INDUSTRY

The energy industry has evolved with the industrialization of the world economy and rising consumer incomes. Many sources of energy have been important in human history, including dung, timber, and whale oil. The modern energy industry, however, is focused primarily on coal, crude oil, natural gas, and electricity.

COMPOSITION OF GLOBAL ENERGY CONSUMPTION

As reported in the BP Statistical Review of World Energy, in 2005 oil accounted for 36.4 percent of total world energy consumption, followed by coal at 27.8 percent, natural gas at 23.5 percent, hydroelectricity at 6.4 percent, and nuclear energy at 5.9 percent. The composition of energy consumption differs remarkably across regions due to the relative costs of consuming differing energy sources, as determined by the relative abundance of domestic energy supplies and the stringency of environmental regulation. In North America oil accounts for 40.4 percent of total energy consumption, followed by natural gas at 24.9 percent, coal at 21.9 percent, nuclear energy at 7.5 percent, and hydroelectricity at 5.3 percent. This differs substantially from the composition of total energy consumption in the Asia-Pacific region, for example, where coal is the major energy source accounting for 48.1 percent, followed by oil at 32.6 percent, natural gas at 10.7 percent, hydroelectricity at 4.9 percent, and nuclear energy at 3.6 percent. China and India account for 79 percent of all coal consumption in the Asia-Pacific region and 44 percent of total world coal consumption.

CRUDE OIL MARKETS

Crude oil has evolved from an industry controlled by a small number of vertically integrated companies in which there were few market-based transactions to an industry in which crude oil is a commodity traded on organized exchanges—such as the New York Mercantile Exchange futures contract, which began trading in 1983—as well as on over-the-counter spot markets (Verleger 1982). The distinguishing feature of the crude oil market since 1973 is the resource cartel known as OPEC, the Organization of Petroleum Exporting Countries. The large oil price increases of 1973 and 1979 are generally attributed to the exercise of market power by OPEC, though there are several alternative hypotheses about OPEC’s behavior (Gately 1984). James M. Griffin (1985) and Clifton T. Jones (1990) provide direct empirical evidence on OPEC behavior. Their empirical analyses suggest that OPEC engaged in cartel behavior during periods of rising as well as falling prices. The empirical evidence is also consistent with competitive behavior on the part of non-OPEC producers of crude oil.

OPEN ACCESS ENERGY TRANSMISSION

The recent restructuring of natural gas and electricity industries around the world is based on the separation of the energy commodity from its transmission. These energy industries had been organized as natural monopolies in which a single regulated firm provided service to all customers. Under this organization, merchant transporters purchased energy upstream and resold it downstream. The move toward a system based on a property right in transportation has allowed for multiple owners and promoted a more competitive organization of these energy markets. Through use of transportation rights and
contracts nearly any organizational structure can be created for pipelines and electricity transmission, including all the historical forms of merchant carriage, common carriage, contract carriage, and vertical integration.

When a property right in transportation is issued, for example by a pipeline, the pipeline becomes a supplier of transportation rights rather than a supplier of transportation. The holders of the rights are the ones who supply transportation and this supply is allocated through the market (De Vany and Walls 1994c; Smith et al. 1988). Property rights in transportation capacity have decentralized control, permitting users to acquire transportation interests through purchase or by contract.

NATURAL GAS
Before open access gas transmission there was no competitive market for natural gas (Smith et al. 1988; Teece 1990; De Vany and Walls 1994a; Michaels 1993). Regulators organized the industry as separated monopolies. Transportation and gas were bundled together and buyers and sellers did not have direct access to one another. As a result, gas purchases were made under long-term contract (Mulherin 1986a; Mulherin 1986b). These regulatory policies balkanized the natural gas industry and disconnected the pipeline grid. Even though, over time, a vast grid of pipelines developed to serve users, its competitive power was nullified because the grid was disconnected and gas flows were fixed.

As a result of open access transmission, much pipeline capacity has been reallocated from the pipelines to their customers. In the U.S. interstate gas market, control of transportation has been decentralized, with 1,400 local distributors holding transportation rights on twenty-one major interstate pipelines (Bradley 1991). Open access transmission brought forth new markets where none had existed; over fifty gas spot markets now exist at scattered points throughout the pipeline grid (De Vany and Walls 1994c) and they have been extremely successful in disciplining prices and allocating natural gas (De Vany and Walls 1994b; De Vany and Walls 1996).

ELECTRIC POWER INDUSTRY
RESTRUCTURING
The electricity industry in the United States—and in many other countries around the world—is in the midst of fundamental change as a result of regulatory reform aimed at restructuring the industry, in order to introduce and increase the intensity of competition in wholesale and retail markets. Contrary to the situation in a number of other countries, in the United States restructuring efforts have been hampered by divided regulatory jurisdictions. (See, for example, the discussion in Brennan [2003] for legal and economic perspectives on the roles of different levels of government in a federation.) The federal government has jurisdiction over wholesale electricity sales and movement because electricity at the wholesale level crosses state borders and therefore qualifies as interstate commerce. (In addition to interstate trade, there is substantial Canada–U.S. trade in electricity that adds another level of institutional complexity. See Feldberg and Jenkins [2003] for a brief legal and institutional analysis of this issue.) Retail markets, on the other hand, are under individual states’ jurisdiction. This historical fact has led to a patchwork of different rules and regulations governing electricity markets.

Currently, according to a 2002 U.S. General Accounting Office report, twenty-four states and the District of Columbia have enacted legislation or issued regulatory orders to open their retail markets to competition. However, of these, seven states have either delayed or suspended implementation of restructuring and the remaining twenty-six states have not yet taken any steps to introduce competition at the retail level. The result of this divided jurisdiction and diverse approaches to restructuring has been the introduction of a great deal of regulatory uncertainty into the market. This uncertainty is having an impact on the development of new generation facilities.

POWER PLANT INVESTMENT
One key feature of restructuring has been a move away from centralized planning of new generating capacity and transmission upgrades by utilities and state-level public utilities commissions. Instead, a decentralized process of development and investment decisions—largely by non-utility companies—is evolving. The development plans of these companies are not subject to approval by public utilities commissions nor are they coordinated by a central body. Because the development process can be long, regulatory and market conditions may change considerably, causing developers to reassess the relative merits of each of their projects during development, in response to both volatile energy prices and long and uncertain state and federal approval processes.

Power plant investment is higher in states that have restructured electricity markets than in states that have taken no restructuring actions (Walls, Rusco, and Ludwigson, in press). Development is also more prevalent in areas of the country with a robust wholesale market infrastructure. Ownership of new power plants also differs across states, with non-utility companies accounting for the bulk of new power plants in states taking restructuring actions, while utilities still have a strong or dominant role in new development in states that have not restructured at all. States’ decisions to implement retail competition result in more investment in new power plants.
NUCLEAR POWER
In 2005 there were 440 operating nuclear power plants in thirty-one countries and these accounted for 16 percent of the world’s electricity supply (World Nuclear Association 2005). However, with few exceptions, there has been no new construction of nuclear power plants in the restructured electricity markets. Nuclear power plants have been plagued by problems of public acceptance and waste disposal. There are also important regulatory and financial issues that act as disincentives to the development of nuclear generating plants in liberalized power markets. Nuclear power plants are unattractive to for-profit electricity generation companies due to the extremely large up-front cost associated with nuclear construction and the large correlation between electricity prices and fossil fuel prices. Merchant power producers are interested in locking in the spread between input and output prices. When power prices fall, fuel input prices also fall for conventional fossil-fueled power plants. However, nuclear plants are extremely unprofitable under this scenario, leading to the decision of most private investors to not choose nuclear power units (Roques et al. 2006).

ENERGY AND THE MACROECONOMY
James Hamilton (1983) presented the first systematic analysis of the effects of oil price shocks on the macroeconomy. His research suggested that the two large price increases in crude oil in the 1970s had a significant real economic impact, lowering economic growth in the United States. However, subsequent empirical analysis has found that this relationship may in fact be asymmetric; Knut Anton Mork (1989) found that shocks increasing oil prices were associated with lower economic growth, but that oil price reductions has no impact on real economic activity. More recent analysis that includes the oil price shocks associated with the Iraqi invasion of Kuwait find that the relationship between energy and macroeconomic activity is very weak, even allowing for asymmetries (Hooker 2002; Barsky and Kilian 2004).

ENERGY AND LABOR
Working conditions and salaries in the energy industries largely reflect the overall labor market conditions for any particular time period and geographic location under consideration. However, one notable difference between the energy industry and most manufacturing or service industries is the requirement that a combination of technical and blue-collar workers be physically present at the specific location where energy resources are extracted from the earth. In the United States—home to most of the world’s multinational energy companies and to a large pool of skilled and unskilled labor—this historically led to the formation of communities in the locations where energy supplies were discovered. In other countries where large multinational energy companies operate—such as Nigeria and Russia—a combination of domestic blue-collar migrant workers and expatriate technical workers are employed in energy extraction.

BIBLIOGRAPHY
ENERGY SECTOR

Twentieth-century affluence in the industrialized countries relied on the highly concentrated energy found in fossil fuels, especially easily accessible oil. Steep increases in the productivity of workers resulted in economic growth and rising household incomes, which transformed the experience of everyday life. In particular, automobile-dependent suburbs spread, and increasingly larger living spaces became filled with electrified appliances of all descriptions.

The industrialized countries, with less than 20 percent of the world’s population, still use more than 60 percent of all primary energy. However, most future growth in production and consumption will take place in developing countries with huge populations eager to emulate lifestyles of the affluent. A pressing question is how future demand for energy can be accommodated.

With most commercial energy long provided by fossil fuels, networks of facilities for prospecting, extracting, refining, and distributing are well established. But the richest oil reserves are being depleted, and alternatives to fossil fuels—nuclear power and various forms of renewable energy—pose a variety of challenges requiring substantial investments in research and infrastructure. Such investments will be forthcoming only when alternatives such as nuclear power have long-term prospects for social acceptability, which is necessary for profitability.

Since energy is required for all aspects of production and consumption, a sharp increase in its price can have a substantial dampening effect on the entire economy. The experience of the oil embargo by the Organization of Petroleum Exporting Countries (OPEC) and sharp increases in oil prices in the 1970s demonstrated the vulnerability of even the most powerful oil-importing countries and their susceptibility to panic, inflation, and recession. Some of the incremental wealth amassed by oil exporters ended up as loans to developing countries (in part to pay for oil) that they were unable to reimburse. Such a sequence of events could easily be repeated.

The history of human use of fuels and minerals has been a race between the exhaustion of the richest deposits, which bids up the price, and the development of powerful new technologies that lower the costs by exploiting lower-quality resources or obtaining more work per unit of raw-energy input. Temporarily higher prices for oil could stimulate massive investments in research and infrastructure to expand the long-term supply of energy from unconventional sources. However, the costs and risks, including those associated with the inevitable environmental impacts, may be extremely high. In parallel with the search for new sources of supply, the effective demand for energy services needs to be substantially reduced by changes in the energy-intensive lifestyles made possible by cheap oil.

Lifestyle decisions about housing, mobility, and diet have the most impact on household demand for energy. The affluent have come to require diets rich in animal products, foods transported long distances, large housing spaces with year-round temperature controls, personal cars for trips to work and shopping, and air travel for recreation. It remains to be seen if a marked shift in
lifestyles can be achieved voluntarily, either as a response to crisis or in search of what has been called a “new American dream.” One hopes that the race to build consumer societies in developing countries can be based on more sustainable lifestyles. While engineering research and corporate research and development focus on new technologies for enhancing energy supply and improving efficiency, social scientists face the double challenge of developing credible scenarios involving sustainable lifestyles and evaluating possible ways to achieve those scenarios.

1936–

Stanley L. Engerman, the John H. Munroe Professor of Economics and History at the University of Rochester, was born in New York City on March 14, 1936. Engerman, who received BS and MBA degrees from New York University and a PhD in economics from Johns Hopkins University, is a pioneer and major figure in the branch of economic history called “new economic history” or “cliometrics,” a term that marries the muse of history—Clio—to the statistical analysis of data, emerged in the 1960s to become a central approach in addressing historical questions.

Engerman is best known for his work on slavery, especially his research with Robert Fogel on the U.S. South. Their two-volume book Time on the Cross, published in 1974, revolutionized the historical interpretation of the slave system. By combining the wealth of information that they collected from slave plantations and other sources and employing the techniques of the new economic history, Fogel and Engerman overturned accepted views.

Engerman and Fogel argued that economic incentives of owners and slaves were central to the way slavery functioned. They found that by the approach of the Civil War in 1860, the system had never been stronger economically. Slaves were selling at record high prices, and slave owners enjoyed substantial profits, especially on the larger plantations. Engerman and Fogel showed that, although violence or the threat of violence was part of the life of a slave, positive incentives in the form of better material conditions and even cash payments led to a slave labor force that was highly motivated. Through the statistical analysis of farm data, they also showed that productivity levels were higher than on free farms, especially so on plantations, where cotton was produced using gang labor. Their main conclusions were criticized at first but are now widely accepted.

Engerman’s study of slavery has extended to the Caribbean and other parts of the world, where his emphasis has been on the process by which the slaves ultimately gained their freedom. Engerman has often been at the epicenter of the debates about slavery and emancipation; in his presidential address to the Economic History Association in 1985, he summarized some of these debates. Engerman points out that whereas the colonies of mainland North America were settled largely by Europeans, the rest of the Americas received many more immigrants from Africa, who were forced there by an active slave trade. Engerman has helped describe the slave economies, which by the middle of the nineteenth century were producing much of the world’s sugar, cotton, coffee, and tobacco. He has also explored the transition of these economies to free labor. Unlike in the United States, which ended slavery through a bloody Civil War, slave emancipation in the rest of the Americas was largely peaceful. Engerman again highlights the importance of economic incentives, showing that, in contrast to what happened in the United States, slave owners in the British colonies received cash compensation for their emancipated slaves. As well, former slaves were required to work for a period of time under regulated conditions, further reducing the cost of emancipation to the owners and easing the transition to free labor.

In the late twentieth century Engerman’s work helped get to the heart of economic growth. During the nineteenth and twentieth centuries the economies of the United States and Canada were among the most successful in terms of total output and output per person, whereas other parts of the Americas fell far behind. Yet in 1800 the Caribbean and other regions based on slavery had been among the world’s wealthiest, indeed much wealthier than the free Americas that later did so well. Working mainly with Kenneth Sokoloff, Engerman has argued that although the slave system could generate high levels of output and large profits for slave owners, the
extreme levels of inequality led to institutions that could not sustain growth once slavery was abolished. Most importantly, inequality discouraged the flowering of democracy and the establishment of an effective schooling system.

The archetypal inductive scholar, Engerman has been adviser to generations of students and colleagues. In Slavery in the Development of the Americas (2004), an edited volume based on the papers of a conference held in Engerman’s honor, David Eltis wrote that “his office (with its triple layer of books lining the walls) and home have functioned as a crossroads and clearing house for nearly four decades, not just for new ideas, but also for scholars seeking intellectual assistance and commentary” (Eltis, Lewis, and Sokoloff 2004, p. viii). Engerman has served on numerous editorial boards and edited more than fifteen books, many of which have been highly influential, particularly The Reinterpretation of American Economic History (1971), coedited with Robert Fogel; Long-Term Factors in American Economic Growth (1986), with Robert Gallman; A Historical Guide to World Slavery (1998), with Seymour Drescher; and the three-volume Cambridge Economic History of the United States (1996, 2000), coedited with Robert Gallman.

Engerman also has published more than one hundred articles in leading academic journals and edited volumes. Most of these deal with issues associated with slavery, but his work has spanned areas as diverse as fiscal policy, education, international trade, population and migration, industrial development, and the long-run process of economic growth. In addition to being a former president of the Economic History Association, Engerman is a Distinguished Fellow of the American Economic Association.

ENGINEERING

Engineering is a body of complex knowledge and a sophisticated art. Because it incorporates mathematical and physical sciences in its applications and designs, it is often mentioned together with science. Engineers, however, deal with the operation of things and apply scientific methods to understand and solve problems, whereas scientists focus on the discovery of knowledge. The traditional role of engineering is to apply natural laws in order to meet the practical needs of society. The scope of engineering is broad, ranging from designing a paper clip, to building space shuttles for space missions, to inspecting the Eiffel Tower.

Engineering is of great importance to modern societies. Participation in engineering, however, is closely linked to gender and race. Historically, engineering, like other intellectual endeavors, was considered a white male domain. Women and racial minorities were virtually absent from the development of engineering as a profession, but not because there were no females or minorities with technical knowledge and expertise. Many female and black inventors remained unrecognized because of economic, legal, and political barriers. Cultural assumptions about the “proper” roles of women and minorities and discriminatory practices, both individual and institutional, discouraged and restricted creative activities among women and minorities. This traditional negating of the intellectual achievements and abilities of women and minorities had a long-term adverse impact on female and minority participation in and contribution to engineering.
Engineering education and employment has become more inclusive, due to a variety of progressive reforms, such as the Civil Rights Act (1964), Title IX of the Education Amendments (1972), and affirmative action programs. Furthermore, industrialization and development in defense and information technology industries have created a rising demand for technical workers. As a result, employers turn to nontraditional workers—women, minorities, and immigrants—as an additional source of skilled labor.

The notion that there is a male culture of engineering has been invoked to account for existing gender disparities in the engineering profession. Due to gender role socialization, women tend to lack “tinkering” experience in childhood. This deficit in technical skills presents challenges for female college students in predominantly male fields such as engineering. It has been suggested that the masculine nature of technological work and male dominance in the workplace have made it difficult for female engineers to fit in. The dearth of women in engineering fields in turn helps perpetuate the male culture of engineering.

Prior to 1880, engineering practice in the United States was primarily a private, independent endeavor, but since then it has become institutionalized and professionalized. By contrast, in Britain engineering is still considered a craft-based occupation rather than an elite profession. A traditional emphasis on apprenticeship as the means to obtain practical skills and experience sets British engineers apart from their American counterparts, who undergo formal training in engineering science. In Britain, neither the government nor the private sector has a significant role in the development and expansion of engineering education. It has been argued that the focus on training through apprenticeship limits the development of science-based high-tech industry, and that the “craft” model is responsible for Britain’s economic decline.

The British engineering population can be categorized into three groups: chartered engineers, technical engineers, and technicians. Unlike autonomous managers, British engineers who perform non-manual technical work enjoy a marginal status in the organizational structure. They organize themselves by unions instead of opting for professional structuring. As a result, engineers in Britain occupy a relatively low social status compared to their European and American counterparts.

Unlike the British, the French rely on elite engineering schools to produce their technical experts. French engineers put a premium on theoretical knowledge. They tend to identify themselves more with high-status management than with low-status technical staff and, as with their American counterparts, they are expected to join the ranks of management. Having formal training in mathematics and science prepares them for their managerial careers. The French engineering workforce is highly stratified, based on divisions among academic institutions and among employers. The same can be said about the German engineering community. However, instead of concentrating on abstract knowledge and basic research, the training of engineers in Germany has incorporated practical training into engineering science. German engineers have played a key role in the nation’s industrialization. The vast majority of them are employed by the state and industry.

Engineering in the United States is not a homegrown product. The American engineering profession began to take shape after European engineering practices were introduced into the United States. The government, industry, and academic institutions have collectively shaped the professionalization and internationalization of engineering. Professional engineering in the United States evolved as a synthesis of the British “craft” system, with its focus on the practical and empirical; the French “school” system, with its emphasis on formal and theoretical training; and, later, the German “estate” model, with its orientation toward research. During the nineteenth century, most American engineers were trained on-the-job or through apprenticeship in a machine shop. The British “craft” method became the training system for many American civil and mechanical engineers. Others received formal training at military academies, such as the United States Military Academy at West Point. Gradually, civilian engineering schools replaced military academies as the principal training ground for engineers. After the passage of the Morrill Act by Congress in 1862, civilian engineering schools became the principal producers of engineers. Under this act, the federal government offered land grants to states for the establishment of schools or college programs in engineering. Many academic institutions took advantage of these land grants and began to offer courses in engineering. As the professionalization of engineering took shape, new engineering fields began emerging in the late nineteenth century. Meanwhile, the influence of business and industry on formal engineering training became increasingly stronger. Besides land, a lot of resources are required to set up an engineering school, including expensive laboratory equipment. Through their financial backing of engineering schools and to a lesser extent the training of engineers at their own company schools, business and industry have exerted direct, strong, and enduring influence over engineering curricula as well as the supply of engineers. As a result, the private sector has become a major sponsor and beneficiary of university engineering schools. Although universities have assumed the role of educating engineers, the private sector has maintained its control over engineering education by
offering critical financial backing to engineering programs across the country, new and old.

Economic integration and expanding free trade have made engineering a complex global endeavor transcending national boundaries. With the advent of information technology and advanced telecommunications, transnational projects involving engineers from different cultures are not uncommon. Collaborations in research and development between engineers and scientists from diverse backgrounds are also routine. Engineers can be found in both public and private sectors, and enjoy enormous influence in business and industry.

Engineering is manifested in many facets of our lives. At the end of the twentieth century, the integration of engineering with disciplines such as mathematics, cognitive science, and artificial intelligence resulted in the creation of computer science and information science programs at universities. Many medical applications—such as robotics, artificial organs, radiology, and ultrasound—are the culmination of research pairing engineering and other disciplines.

Because technical competence is so critical for business and industry, engineers have become very much part of the modern system of technocracy, or rule by experts. “Engineer-inventors” believe that they can offer technical, logical, and practical solutions to social problems and, eventually, facilitate social progress. Indeed, no one can deny that technological developments have transformed the structure of society and changed our work and lifestyles. Very few people have any real knowledge of the planning, design, and evaluation associated with the creation and maintenance of utilities, buildings and other structures, machines and equipment, and a host of commercial products. But for many people, a world without automobiles, computers, and mobile phones would be unthinkable. Like managers, engineers are trusted by employers to perform sophisticated tasks with little or no supervision. For these reasons, engineers, who enjoy relatively high prestige in many countries, have been called the “production arm,” “trusted workers,” and “symbolic analysts.”

Technological inventions and innovations have served diverse economic, cultural, and political purposes. On the one hand, in democratic societies technology can be a constructive tool used to foster positive social change. On the other hand, it can also be a destructive force, used by a ruling class to preserve domination and control over the masses. Thus, despite the universal applications of engineering designs, engineering is never truly value-neutral.

ENLIGHTENMENT

“It was the common presupposition of all thinkers of the Enlightenment that the being of man is implied in and subordinated to the being of nature and that it must accordingly be explained by the same universal laws” (vol. 5, p. 548). So wrote Ernst Cassirer (1874–1945) in the entry on “Enlightenment” in the original Encyclopedia of the Social Sciences (1931). To the Dutch philosopher...
Baruch Spinoza (1632–1677), Cassirer attributed the idea that the “stirrings and movements of the will on which the world of man is founded are subject to rules just as universal as the movements within the world of physical bodies. There is a mechanics of human inclinations and urges…. This analogy was emphasized so severely by the philosophy of the Enlightenment that it became finally a complete logical identity” (vol. 5, p. 548).

A generation later Hayden White wrote, “It follows that the Enlightenment was altogether misguided in its attempt to construct a science of human nature on the basis of a study of physical nature: understanding cultural phenomena, which are creations of man alone, in terms of incompletely understood natural principles is doomed from the start” (White 1968, vol. 16, p. 314). This passage appeared in the entry on “Giambattista Vico” in the first edition of the International Encyclopedia of the Social Sciences (1968), published in an age in which the Enlightenment had fallen on such hard times that it did not even rate a separate entry in that Encyclopedia. The inclusion of the present entry in this second edition is indicative of the rising fortune of the Enlightenment not only in its own right but also with respect to the social sciences specifically.

From the 1970s to the 1990s, there were several attempts to place the origins of the social sciences in the eighteenth century. Yet, although the term la science sociale was first used around the time of the French Revolution (1789–1799), a consensus has emerged that, whatever was invented by eighteenth-century social theorists, it was not modern social science. When the editor of History of the Human Sciences devoted an issue (6 [1] 1993) of that journal to the Enlightenment origins of the social sciences, he received a set of articles that called that very premise into question. Christopher Fox wrote that “we cannot visit the eighteenth century with a modern campus map” (Fox et al. 1995, pp. 3–4). Claude Blanckaert asserted that to name the Comte de Buffon (1707–1788) as the founder of modern anthropology is really to say that Buffon is the earliest author read by modern anthropologists. Roger Smith contended that it is no longer tenable to trace modern disciplines like sociology, psychology, anthropology, and economics back to Enlightenment precursors, as was the practice in many histories of the disciplines throughout the twentieth century. With the expansion of the eighteenth-century canon since the 1970s, historians of the social sciences have found that the configurations of eighteenth-century science, politics, and social theory were much more complicated than indicated by the tidy narratives of Enlightenment and revolution that characterized much of twentieth-century scholarship.

It was against those narratives of individual liberty, limited government, and toleration of religious practice that continental historians in the mid-twentieth century set up an alternative narrative of Enlightenment social science: one that emphasized efficiency in government, technical bureaucracy, and the assimilation of populations into a centrally administered territorial nation-state, all of which converged for one purpose—domination.

Max Horkheimer (1895–1973) wondered how the liberal project of the Enlightenment could have culminated in the authoritarian regimes, death camps, and armed conflict of the twentieth century. Where Vico saw the project of a mathematical, laws-based social science as doomed from the start, Horkheimer found that, in historical terms, that project was only too successful. As enlightened science played out in the nineteenth and twentieth centuries, all particulars came to be understood as mere representatives of universals. All qualities were reduced to quantities, and all things ultimately became identical, including people. The Enlightenment, wrote Horkheimer, represented the triumph of oppressive equality. Quantitative methods became so pervasive that the human and natural sciences, initially intended to eradicate irrational appeals to myth, magic, and religion, became mythic in their own right.

Under the old regime, domination was clearly visible in political and ecclesiastical hierarchies and in the dogmas by which they were legitimized. The Enlightenment produced new forms of domination that were even more insidious because they were not only vindicated by critical reason but were also applied by reason itself. Michel Foucault (1926–1984) characterized every victory of enlightenment as a step further into the darkness of domination. Biology and medicine exposed to light the hidden recesses of the body in search of life, but found only disease and death. Psychology penetrated the rational mind only to discover irrationality and insanity. Prisoners were freed from dungeons only to be captured all the more securely in the light that flooded Jeremy Bentham’s (1748–1832) Panopticon prison, and, not only for criminals, the entire world became a prison that subjected the individual to every form of manipulation and control. Language itself was appropriated by reason (and later by positivism), so that every attempt to resist enlightenment only served the cause of enlightenment. Theory was rendered irrelevant. Critique, once the hallmark of the Enlightenment, came to be dismissed as mere belief or ideology, or worse, as art. In place of the human spirit and critical inquiry was the commodification of all things—science and language as well as material culture—and Horkheimer proposed a theorem that the pliability of the masses increased as the quantity of commodities offered to them increased. Even the individual’s own self became alienated and objectified through technologies of psychology.
Against the poststructuralist attack on the Enlightenment, several studies have highlighted the intellectual and social network of the international republic of letters that enabled individuals and texts to cross national boundaries and find common ground in ideologies of republicanism, universal human rights, toleration of beliefs and practices, and freedom of thought, all of which went under the heading of “cosmopolitanism.”

Despite the reservations of Europeans regarding the legacy of their own supposed Enlightenment, the traditional narrative of Enlightenment liberalism has been appropriated by social theorists in regions briefly (although brutally) colonized and dominated by the European states in the nineteenth and twentieth century. “Post-colonial scholarship is committed, almost by definition,” wrote Dipesh Chakrabarty, “to engaging the universals—such as the abstract figure of the human or that of Reason—that were forged in eighteenth-century Europe and that underlie the human sciences” (2000, p. 5). He finds that although it is inadequate, the European narrative of Enlightenment and technological advancement is indispensable to understanding the history and future of “developing” nations. But this was precisely the point made by the poststructuralists: that cosmopolitanism, like all universal systems, was artificially homogenizing. Responding to Immanuel Kant’s (1724–1804) “history of pure reason” at the end of the Critique of Pure Reason (1781), Johann Gottfried Herder (1744–1803) wrote a Metacritique (1798) that argued that there was no such thing as “pure” reason. There was only particular reason. That is, there were no universal ideas or truths, no world soul into which all particular souls were tapped. There were only particular, unique, historical communities, and these were easily extinguished by totalizing systems like universal reason and imperialism of all sorts, whether ancient Roman or modern European. Universal reason was a chimera, perpetual peace a pipe dream.

It was not merely the case that the party of humanity, as Peter Gay called the two dozen or so philosophers who comprised the twentieth-century canon of eighteenth-century thought, was shouted down by counter-enlightened conservatives and reactionaries. The tendency toward mass democracy and domination, both physical and psychological, was never a sinister plot of imposters. It was built into the very Enlightenment itself—built, that is, into cosmopolitanism, universal reason, and the instrumental reason aimed at reforming the inefficiencies and abuses of old regime society.

Writing on the twentieth-century culture industry, Theodor Adorno (1903–1969) augmented Horkheimer’s penetrating critique of the technological society by showing that even the objects of individual choice were instruments of homogenizing conformity. Production technology, hailed in the eighteenth and nineteenth century as the means by which Europe could finally cultivate the land and meet its needs efficiently so that the individual could cultivate himself or herself, was transformed into the economic logic of standardization and mass consumption. One city, with its gleaming skyscrapers, was essentially the same as the next. Older houses outside the city center decayed into slums, while new suburban houses were thrown up quickly and cheaply, as if designed to be discarded in a short while like empty food cans. Suburban housing projects were intended to perpetuate the rational-critical individual as an independent unit in a small hygienic dwelling, but in fact they made the individual all the more subservient to the absolute power of capitalism. Adorno took the development from telephone to radio as indicative. The telephone was liberal: it allowed the person to play the role of subject. The radio was democratic: it turned all participants into listeners, authoritatively subjecting them to broadcast programs that were all exactly the same. Other mass spectacles performed the same function, including popular music, cinema, and sports, to say nothing of television. Focus groups and market research, employing the techniques of propaganda, ensured that something was provided for all so that none might escape. Even improvisational jazz was a perfected technique that homogenized all particulars into a universal jargon of style, a style that, in Friedrich Nietzsche’s (1844–1900) terms, was “a system of non-culture, to which one might even concede a certain ‘unity of style’ if it really made any sense to speak of stylized barbarity” (Nietzsche 1917, p. 187; Horkheimer and Adorno 1972, p. 128).

Deeply implicated in the movement from liberal Enlightenment to mass deception were the social sciences. Adorno characterized that movement as an inexorable trend built into the Enlightenment itself. But social scientists themselves worried about their own role in social engineering and manipulation.

Both the modernist view of Enlightenment liberalism as an alternative to twentieth-century totalitarianism and the postmodernist view of the Enlightenment as the source of that same totalitarianism depended on selective readings of eighteenth-century social theorists. In fact, few in the eighteenth century were as sanguine about the power of light and reason as they were made out to be in the twentieth century. Edmund Burke (1729–1797) worried about a world in which power became gentle, obedience became liberal, and all shades of life were harmonized, blandly assimilated, and dissolved. Justus Möser (1720–1794) asserted that the civil administrator who hoped to reduce everything to an academic theory or a few rules paved the road to despotism and lost the wealth of variety. Whether in local administration or global ethnology, particularist sentiments like these were echoed across the continent by
social theorists such as Louis François Jauffret (1770–1840), Aubin Louis Millin (1759–1818), Joseph-Marie Degérando (1772–1842), Johann Jakob Moser (1701–1785), Ludwig Timotheus Spittler (1752–1810), Christoph Meiners (1747–1810), Johann Georg Hamann (1730–1788), and of course Herder. Historical scholarship since the mid-1970s has also celebrated the variety of eighteenth-century social thought in counter-Enlightenment, radical Enlightenment, Enlightenment in national context, and so forth. Just as social science cannot be taken as monolithic, neither can the Enlightenment.

ENTERPRISE
An enterprise is a business venture initiated by an entrepreneur, the person who assumes the organization, management, and risks of a business enterprise. Entrepreneurship is considered a factor of production that involves human resources, most commonly performing the functions of raising capital; organizing, managing, and assembling other factors of production; and undertaking business decisions. It involves a combination of initiative, foresight, and willingness to take the risks and undertake the new ventures required to establish a successful business.

The term entrepreneur (and consequently enterprise) appears to have been introduced by the Irish banker and economist Richard Cantillon (c. 1680–1734). The term was popularized as a result of John Stuart Mill's classic work, Principles of Political Economy (1848). To the classical economist of the late eighteenth century, the term described an employer, in the character of one person, who assumed the risk and management of an enterprise. In practice, entrepreneurs were not differentiated from capitalists until the nineteenth century, when their function developed into that of coordinators of processes necessary to large-scale industry and trade. At that point, much like today, the entrepreneur was involved in the management of the enterprise, in contrast to the ordinary capitalist, who merely owned an enterprise and might choose not to take any part in the day-to-day operation. Henry Ford is an example of the rising class of entrepreneurial manufacturers in the twentieth century in the United States of America. However, the entrepreneur's functions and importance have declined with the growth of the corporation.

Nevertheless, the term entrepreneur had disappeared from the economics literature by the end of the nineteenth century. This was due to the fact that economists began to use the simplifying assumption that all individuals in an economy have perfect information. Under this assumption, there is no reason for an entrepreneur, or an enterprise, to exist. If individuals have perfect information, they will all make the same assessments of alternative economic activities. More recently, however, economists have increasingly removed this unrealistic assumption of perfect information, allowing once again for the presence of entrepreneurship in the literature. In addition, entrepreneurship has been added as the fourth production factor, after labor, capital, and natural resources.

Almost any business or organization can be called an enterprise, and an enterprise can be either private or public in nature. A private enterprise is a business organization especially directed toward profit and generating personal wealth for the owners. In other words, the owners and operators of a private business have as their main objective the generation of a financial return in exchange for their expense in time, energy, innovation, skills, and money. The private enterprise is the main institution of market capitalism, and as the price mechanism is a co-
coordinating instrument, the entrepreneur performs a coordinating function. Free enterprise, which is the result of free markets, is another term used to denote market capitalism. Indeed, the terms enterprise, company, corporation, and organization are often used synonymously.

A firm is a unit that employs factors of production to produce goods and services. A firm is a commercial partnership comprising a collection of individuals grouped together for economic gain, especially when unincorporated. It is represented by the name or designation under which a company transacts business. The term became popularized in Ronald Coase’s 1937 article, “The Nature of the Firm.” Operating within a market involves some costs, but by establishing a firm and the authority to direct resources, certain costs are reduced. As Coase states, “When the direction of resources (within the limits of a contract) becomes dependent on the buyer in this way, that relationship which I term a ‘firm’ may be obtained” (Coase 1937, p. 392).

In an article published in 1972 in American Economic Review, Armen Alchian and Harold Demsetz defined a firm as a contractual subject to continuous renegotiation with the central agent, or the firm’s owner and employer. Thus, a firm is a hierarchical organization attempting to make profits. There are various types of firms, such as: (1) a sole trader or sole proprietorship, in which there is only one owner of the firm with unlimited liability; (2) a partnership, in which there are two or more partners who own, control, and finance the firm and have unlimited liability; (3) a private limited company (Ltd.) or corporation, in which a limited number of shares are issued and the firm is owned by shareholders who have limited liability. In the latter case, these corporations are legal entities, and the firms or corporations owned by the shareholders are treated by law as an artificial person.

By the latter half of the nineteenth century, corporations increased substantially, displacing other forms of enterprises. The control of industrial production thus became the responsibility of corporate finance, resulting in what the Norwegian-American economist Thorstein Veblen (1857–1929) called “absentee ownership.” Often, however, shareholding ownership is so widely dispersed that the majority of shareholders reluctantly experience the separation of ownership from control. That is, control can be maintained by a minority interest with access to corporate finance: “ownership continually becomes more dispersed; the power formerly joined to it becomes increasingly concentrated; and the corporate system is thereby more securely established” (Berle and Means 1933, p. 9). According to Veblen, absentee ownership has grave consequences for the structure of the society, because “law and politics … serve the needs of the absent owners at the cost of the underlying population” (Veblen 1923, p. 6).

When an enterprise has operations in more than one country, this enterprise is named a multinational enterprise (MNE), a multinational corporation (MNC), or a transnational corporation (TNC). Such a firm engages in foreign direct investment (FDI) and owns or controls income-generating assets or value-adding activities in more than one country. A multinational enterprise can participate in the economic activities of a foreign country through five general means of involvement: (1) trading (importing or exporting, and incorporate transfers); (2) foreign direct investment (such as joint ventures, wholly owned subsidiaries, green-field FDI, brown-field FDI, acquisition [the firm can have a “majority” or “stake” interest], merger and acquisition, or privatization); (3) indirect (portfolio) investment; (4) agreements that do not involve money transfer from the part of the foreign partner (e.g. licensing agreement, franchising, turnkey projects, or management contracts), and (5) collaboration or strategic alliance with another enterprise in order to cope with pressures of intense global competition and increasingly complex and rapid technological development.

The United Nations and the governments of most developing nations use the term transnational, rather than multinational, to describe an enterprise that has operations in more than one country. The United Nations’ specialized agency, the United Nations Conference on Trade and Development (UNCTAD), for example, employs the following definition: “Transnational corporations comprise parent enterprises and their foreign affiliates: a parent enterprise is defined as one that controls assets of another entity or entities in a country or countries other than its home country, usually by owning a capital stake. An equity capital stake of at least 10 percent is normally considered as a threshold for the control of assets in this context.” Actually, this 10 percent rule has been accepted by the International Monetary Fund (IMF) and the Organisation for Economic Co-operation and Development (OECD), thus identifying this to be the minimum equity stake for an investment to qualify as foreign direct investment and not a portfolio investment.

**ENTERTAINMENT INDUSTRY**

Entertainment as an industry—in the United States alone—is responsible each year for $150 billion in expenditures and some 120 billion hours of consumed time (Vogel 1998, p. xvi). Entertainment as an economic sector consists of diverse products and services including motion pictures, television, music, broadcasting, print media, toys, gaming, gambling, sports, and fine arts.

**ECONOMIC DEVELOPMENT AND THE DEMAND FOR LEISURE**

Leisure time has been a determining factor in the development of recreation and entertainment as an industry. Entertainment has grown as an industry in step with increased income and time available for leisure and recreation. Economic development, often quantified in terms of productivity or output per person-hour, has enabled goods and services to be produced with fewer labor inputs. The growth of the entertainment industries has been directly related to the development of a modern economy and rising economic productivity, though precise estimation of the demand for leisure is a thorny task (Owen 1971). An important issue in the development of entertainment as an industry is the rising productivity of workers, and in particular the ways in which technical progress has increased worker productivity. Progress in technology, in addition to creating the demand for entertainment products and services, has also led to the creation of much of the dominant forms of contemporary entertainment.

**INDUSTRY OVERVIEW**

Substantial production in the creative industries takes place within the U.S. economy and creative products are a major U.S. export. Motion pictures, home video and television programming, music and sound recordings, books, video games, and software are collectively one of the largest and fastest-growing economic sectors, responsible for about 6 percent of total U.S. gross domestic product per annum (Motion Picture Association of America 2006a). Multinational entertainment/media conglomerates such as Vivendi, Sony, and AOL/Time Warner are increasingly becoming dominant in this sector, with operations that permit substantial economies across the line of entertainment products. The process often begins with a literary work of fiction, which is then made into a motion exhibited in cinemas and later on syndicated and network television domestically and abroad, and finally released on home video. Characters and other elements from the movie can be developed into a line of toys cross-promoted with fast food, and further developed into a video game or board game, and perhaps even featured in a line of clothing.

In the motion-picture industry, the sector of entertainment with the highest profile, domestic (U.S. and Canadian) box-office receipts accounted for about $9 billion, while worldwide box-office revenue was over $23 billion for 2005 (Motion Picture Association of America 2006b). The international market now yields more revenue than the North American market and it is also the source of revenue growth for the motion-picture industry, though success in the international market is largely conditional on success in the North American market. The dominance of Hollywood films in worldwide box-office revenue gives rise to claims of cultural imperialism, though major Hollywood studios in fact design films for distribution in the worldwide market even though the films are screened in North America first. While international box-office revenues have been rising, the major sources of new revenues for the motion-picture industry have been from home video and digital versatile disc (DVD) sales, and from merchandising arrangements such as toys, video games, clothing lines, and other products that are tied to successful motion pictures.

While Hollywood films dominate worldwide box-office revenue, the American film industry does not dominate worldwide production. The Mumbai-based Indian film industry—commonly known as Bollywood because it is the “Hollywood of Bombay” (the former name of present-day Mumbai)—produces more motion pictures each year than any other country. Throughout the 1980s about 250 individual film production companies completed an annual average of about 700 feature films per year with the encouragement of official government policy requiring commercial movie theaters to screen at least one Indian film per show (Gomery 1996). In 2003 the Indian film industry produced 877 feature-length films and 1,177 short films (Central Board of Film
Certification 2006); this contrasts with the 459 new films released in the United States during 2003 (Motion Picture Association of America 2006b).

The music industry consists primarily of the sales of prerecorded music—albums distributed on compact disc and audiocassettes, and singles distributed on compact disc. Music videos are also sold as product in traditional formats. Music is also available in alternate digital formats—including MP3, OGG, and WAV—through Internet retailers. The authorized digital distribution of music content has been overshadowed by unauthorized distribution, both free and for profit, though academic research on this issue is much less clear than one would glean from journalistic reports (as is discussed in more detail below).

Gambling in the United States is popularly associated with the cities of Atlantic City, New Jersey, and Las Vegas, Nevada, which are responsible for 9 and 21 percent, respectively, of the 2005 U.S. annual gambling revenues of about $53 billion (PricewaterhouseCoopers 2005). Native American casino-operators account for over 40 percent of gambling revenues. While the United States is a large gambling market, accounting for over 60 percent of worldwide gambling revenues, substantial new growth in gambling revenues is occurring in international markets, especially in the former Portuguese colony of Macao, which began granting licenses to new casinos a few years after being returned to Chinese sovereignty in 1999. While gambling revenues in aggregate make the United States the largest market, the character of North American gambling is quite different from Asian gambling markets. For example, in horse track gambling the average total amount bet on a race day at a North American track is on the order of $100,000, whereas at Hong Kong tracks and Japanese tracks a day’s bets are on the order of $200 million to $300 million, respectively (Busche and Walls 2000).

Expansion of casino gambling opportunities in Asia, with new casinos in Macao and proposed casinos in Japan, Thailand, Singapore, and Taiwan, together with recent changes in British gambling taxation and online gambling opportunities, make prospects favorable for the expansion of international gambling markets (Paton et al. 2002).

**IMPORTANT CHARACTERISTICS OF ENTERTAINMENT MARKETS**

The entertainment industries differ in important ways from traditional manufacturing and service industries. Richard Caves (2000) enumerates seven ways in which the creative industries—including fine arts, music, and motion pictures—differ distinctly from what he terms the humdrum industries:

1. Neither producers nor consumers know the demand for product until after it is revealed. Creative products and services are “experience goods” and there is symmetric ignorance of information, not an informational asymmetry.
2. The creative talents producing the product care about the creative output explicitly, in addition to their pecuniary compensation in production.
3. The creators engage in joint multiplicative production with an array of diverse inputs in which all inputs are essential, because there is less substitutability than in other production processes.
4. Entertainment products are horizontally differentiated products. Each product is unique and must be experienced before demand is known.
5. Products are vertically differentiated by the quality of the inputs used in production. Furthermore, inputs of different quality levels may be combined—for example, a B-list screenplay and an A-list actor.
6. Profitability depends on temporal coordination and prompt realization of revenues once assets are sunk. Delays may occur once assets have been committed to production.
7. Creative products are durable and this leads to issues regarding rents, collection and monitoring of royalties, warehousing, and retrieval.

The seven features identified by Richard Caves are essential in understanding the markets for entertainment products both qualitatively and quantitatively (Walls 2005). Additionally, the demand for entertainment has two properties that are deserving of our particular attention. The first is that consumption of entertainment requires the time of the consumer. The second is that the demand for entertainment is not fixed in advance of the product being produced; instead, it is discovered by the consumers after the product has been consumed. We will discuss these properties of entertainment demand briefly.

The time-cost element is important in understanding the demand for entertainment, because consumption of entertainment necessarily implies customer-supplied inputs; recognizing this explicitly is essential if we are to understand the functioning of demand and supply in this market. Perhaps the best illustration of this point, in a more general context, is the seminal paper by Arthur De Vany and Thomas Saving (1983). De Vany and Saving demonstrate that when all else is equal, consumption cost is lower for a product that requires less time to consume. Of course, price can be adjusted and this implies a trade-off between time-cost and the monetary price. In the entertainment industry, this may also involve substitution.
across alternative media for a similar product. For example, reading an 800-page book may involve a substantial element of time, but a consumer may substitute a video-cassette or DVD film version of the book to be viewed on a computer or television monitor, or a compact disc or audio-cassette version of the book to be listened to while at home, at work, or while commuting. All of these alternative means of consumption involve tradeoffs in which the time-cost of consumption varies greatly and may be of primary importance in consumption decisions.

The demand for entertainment products is not fixed in advance, but is discovered by consumers as they consume many entertainment products. Understanding this aspect of demand is essential if one is to make sense of many of the entertainment industry’s unique business practices. When movie audiences see a movie they like, they make a discovery and tell their friends about it. This and other information is transmitted to other consumers and demand develops dynamically as the audience sequentially discovers which movies it likes. Supply adapts to revealed demand through flexible exhibition contracts and other business practices that permit the increasing returns in film demand to be realized. For example, early viewers of a motion picture may substantially affect the choices of other potential viewers. This type of behavior is known in the social sciences as, variously, herding, contagion, network effects, bandwagons, path-dependence, momentum, and information cascades (Arthur 1994; Banerjee 1992; Bikhchandani et al. 1992). The particular algebraic models of this behavior differ in the mathematical details, but they are all dynamical processes: Demand depends on revealed demand. As a result of this sequential demand process, initial advantages in movie attendance can lead to extreme differences in outcomes when demand has recursive feedback. De Vany and Walls (1996) showed that box-office revenues have a contagion-like property where the week-to-week change in demand is stochastically dependent on previous demand. A big opening of a bad movie can cause consumption to evaporate. But a big opening of a good movie can lead to an avalanche of attendance. Demand for movies, music, fashion, and other entertainment products and services are characterized by extreme uncertainty due to the nature of dynamical demand.

THE CHALLENGE OF PIRACY

The most substantial challenge facing the entertainment industry is intellectual property piracy, largely due to the easily copyable digital format of many entertainment products. Infringement of copyrights and other forms of intellectual property is a large and growing problem around the world and it is of particular importance for the entertainment industry. The Motion Picture Association of America estimates that losses due to piracy exceed $3 billion annually in potential worldwide revenue (Motion Picture Association of America 2005). The intellectual capital of the S&P 500 companies is worth 3.4 trillion U.S. dollars (Bowers 2001), so it follows that even a small percentage infringement on such a large base generates enormous absolute losses to property rights holders. Peggy E. Chaudhry and Michael G. Walsh (1996) provide an overview of trends in counterfeiting in the international marketplace, including a consideration of the legal framework that governs the protection against piracy and a review of different antipiracy strategies.

Piracy of entertainment products can take many forms. These range from illegal copying and distribution of videocassettes and optical media (CD-ROM, VCD, and DVD) to Internet piracy, which can involve commerce and the sharing of digital content. Unauthorized signal transmission and theatrical performances are other types of movie and music piracy. Music and movie piracy are either commercial sale of physical media or the sharing of videocassettes, optical media, and digital content over the Internet.

For most entertainment products the pirate good is identical to the authentic article, except for the packaging and after-sale support. For example, music CDs will be an exact digital copy of the authentic product, but liner notes and lyrics will either be missing or will contain numerous, and often humorous, typographical errors. Many entertainment companies use copy-protection technologies, including the Content Scrambling System for DVDs, dedicated DSL set-top boxes, digital encryption encoding of satellite signals, and Macrovision for videocassettes. The use of antipiracy technologies raises the cost of engaging in piracy, as Sougata Poddar (2003) had modeled analytically. Despite efforts to increase the cost of piracy, however, in practice it is not too difficult even for a computer hobbyist to work around the latest antipiracy technologies (Perry 2005). Even the copy-protection technologies employed in computer software—including online authentication—are quickly rendered obsolete by digital pirates (Harvey and Walls 2006).

Copy-protection technologies, whether effective or not, are aimed primarily at preventing retail products from becoming a source of pirate supply. But the source of pirate movies is often not a retail copy but instead is an insider copy, such as the advance copies used for screening and marketing purposes (Byers et al. 2003). Other copies are made from handheld video camera recordings of motion picture films off of a theater screen. While the quality may be low, the latest movies are also readily available over internet-based file-sharing networks, such as BitTorrent (Kwok 2004). This contrasts with music piracy, in which high-quality copies of songs and entire
albums are available either freely through file-sharing networks, such as those available with the Kazaa program, or available for purchase through for-profit retailers such as allofmp3.com.

Many factors are associated with piracy (Limayem et al. 1999), and according to Seung Kyoon Shin et al. (2004) sociological factors may in fact be more important than some economic factors. Most studies suggest that the level of piracy is systematically related to the level of income. Income reflects a person’s average cost of time and the demand for quality. Patrick J. Harvey and W. David Walls (2003) examined the demand for pirate software in a laboratory study and found that the demand for counterfeit goods decreased as the expected penalty for consuming the illicit goods increased. Income may be correlated with other infrastructure that provides alternative means of consuming the product. All of these factors would be expected to decrease the demand for pirate products as income rises. As average income rises, the supply of pirate products would also be expected to decrease due to the availability of more attractive opportunities for employment than pirating. There is, however, no unambiguous prediction of the equilibrium effect of income changes on piracy.

In a forthcoming article, the present author empirically examines the rate of motion-picture piracy across a sample of twenty-six countries and finds that the level of piracy is explained by the level of income, the cost of enforcing property rights, the level of collectivism present in a country’s social institutions, and the level of Internet usage. Conclusions about the behavioral aspects of piracy are more certain than piracy’s actual impact on the entertainment industry revenues, however: Felix Oberholzer-Gee and Koleman Strumpf (2004) found that Internet music piracy had no negative effect on legitimate music sales; on the contrary, their study found that piracy may even boost sales of some types of music, contradicting the music industry’s assertion that the illegal downloading of music online is causing revenues to fall. In contrast, Rafael Rob and Joel Waldfogel (2006) found that the U.S. music industry lost one fifth of a sale for each album downloaded from the Internet. There is no definitive answer to the question of whether or not piracy has a net negative effect on consumer demand in the entertainment industry.

ENTREPRENEURSHIP

The concept of entrepreneurship and the portrayal of the entrepreneur as leading economic figure, even cultural hero, derive from both the evident nature of the market system and the projected self-image of middle-class business leaders. As with any such concept, its meaning depends on the larger model of which it is a part and its more or less precise relationships to other key figures. Defining the entrepreneur or entrepreneurship deals with a term whose meaning is highly variable in use, and generates serious questions.

The term capital is a creator or (2) finder of opportunities. The entrepreneurship makes to coordination and the projected self-image of middle-class business leaders. As with any such concept, its meaning depends on the larger model of which it is a part and its more or less precise relationships to other key figures. Defining the entrepreneur or entrepreneurship deals with a term whose meaning is highly variable in use, and generates serious questions.

The term capital could refer to all business people, or to only the suppliers of capital, with the others as managers—the promotional, organizational, and operational decision makers—and with the entrepreneur performing a particular function or role, transcending the others. Even that array of possibilities is rendered further complicated by formulations that treat the entrepreneur as either (1) an active promoter or agent of change; or (2) a passive responder to market signals and to change; and either (1) a creator or (2) finder of opportunities.

A troublesome question is whether entrepreneurship refers (1) to a particular function(s) or (2) to persons. If the answer is persons and not function(s) per se, then the correlative question is whether it refers to a particular group of persons or to an aspect of the behavior of all persons. Some individuals may well undertake more and/or more specialized entrepreneurship. But all individuals undertake one or more of the functions of entrepreneurship that can enter the definition of the term—even if it is a matter of reacting to price and other signals in a creative way.

Further difficulties arise when one tries to distinguish the certain behavior(s) or qualities that constitute entrepreneurship, requiring that one identify what makes any activity or quality “entrepreneurial.” But that effort is a part of the larger and vexing question of the definition of entrepreneurship, say, one that does not equate entrepreneurs with business managers as organizers and decision makers.

Two further, interrelated questions are, first, whether the meaning and defense of capitalism involves a system dominated by capitalists and/or entrepreneurs, or a market system of economic agents without such domination, that is, whether capitalism or market economy is the more systemic term; and, second, whether some kind of entrepreneur(ship) has the critical role in all economic systems, i.e., whether only one generic economic system exists and therefore actual economies differ principally in the identity and institutional setting of entrepreneurship.

Several considerations almost invariably enter discussions of entrepreneurship. One consideration is that the entrepreneur is achievement oriented, manifesting the type A personality and always seeking success. The second consideration is that the substantive meaning of achievement is a matter of culture. In market economies, especially capitalist ones, success is achieved through rising in large, important organizational structures, acquisition of wealth, and similar iconic honors. The third consideration concerns the entrepreneur serving as a driving force in the economy, whatever the specifics of its organization and structure. One consideration that often but by no means always enters discussion is the relation of business and governmental entrepreneurs. This relation may take the form of a competition over the use of resources; movement among key leadership positions in private and public sectors; another involves the tendency of entrepreneurs to act up to, if not even beyond, the limits imposed by law.

Definitions typically turn on the incorporation of functions. One definition, centering on coordination, can be close to that of manager or decision maker within the firm; alternatively the usage may turn on the contribution that individual entrepreneurship makes to coordination.
that is systemic, that is, going beyond the firm to the economic system. In either case, the key element is capability in participating in institutionalized decision making processes specializing in the making of policy.

A second function often ensconced within a definition is that of adventurer, the role of formulating a vision and acting upon it. At its most dramatic, this definition tends to make capitalism a civilized game of power in monetary form. This entrepreneur is not content with finding niches or paths not seen by others, and therefore goes beyond finding to creating them themselves. One definition centers on the heroic role itself. This definition recognizes entrepreneurship as a system-specific honorific channel of achievement motivation and/or a designation of such achievement.

Other definitions that incorporate functions are the management of risk or, more properly, uncertainty; the marshalling, management or analysis, and application of information; serving as the adjudicator of conflicting interests within and between firms; and the identification if not creation of opportunities. Some definitions may combine functions, such as innovation under uncertainty and asymmetrical information. Not all definitions apply equally well to both entrepreneurial function and their application to specific individuals.

The concept of the entrepreneur, whether it be understood to pertain to a class of person or an aspect of all agents’ activity or one function or another, is related to other concepts as well. Innovation can result from entrepreneurial activities in in-house or external research and development generating new technology. Both market structure and the form of competition are both influenced by entrepreneurial activity along technological, strategic, and political lines, and influence the form, direction, and mode of entrepreneurial activity. Although much economic theorizing is static, the introduction of entrepreneurship both opens up a wider range of efficient results and multiple paths of economic growth, and the possibility of multiple efficient results and economic-growth paths amenable to entrepreneurial activity. The realm of entrepreneurship is, moreover, transformed by Canadian-American economist John Kenneth Galbraith’s concept of a new industrial state in which corporate and general economic decision making are expanded from the top levels of corporate managements and a mix of government-business antagonism and quid pro quo relationships to decision making lower down in the corporation, in technological and educational elements, and to a system of more or less joint planning for economic stability. In Galbraith’s conception, the entrepreneur is less heroic but no less important a figure.

Finally, attention should be given to Italian economist Vilfredo Pareto’s theory of the circulation of elites and what may or may not be its modern formulation, the market for corporate control and therein competition between entrepreneurs. An alternative formulation juxtaposes individuals with power to competitive forces.

ENVIRONMENTAL IMPACT ASSESSMENT
An environmental impact assessment (EIA) is a planning tool that provides decision makers with an understanding of the potential effects that human actions, especially technological ones, may have on the environment. By understanding the potential environmental effects of an action, policymakers can choose which should proceed and which should not. Governments from around the world perform environmental impact assessments at the national, state or provincial, and local levels. The underlying assumption of all environmental impact assessments is
that all human activity has the potential to affect the environment, and that knowledge concerning the environmental impact of a major decision will improve that decision. As part of an EIA, planners try to find the ways and the means to reduce the adverse impacts of the project and to shape projects to suit the local environment. EIAs can produce both environmental and economic benefits, such as reducing the costs and time needed for project implementation and design, avoiding treatment and clean-up costs, and alerting planners to any potential clashes with laws and regulations.

The original and probably best-known form of the EIA is the environmental impact statement (EIS) used by the U.S. government. The National Environmental Policy Act of 1969 (NEPA) mandates that an EIS must accompany every major federal action or nonfederal action with significant federal involvement within the United States. The precise definition of “major” and “significant” has been very contentious and has resulted in considerable litigation. The NEPA ensures that U.S. agencies give environmental factors the same consideration as any other factors in decision making.

Since 1970 dozens of other nations have established their own versions of an EIA, partly on their own and partly in response to the call of a number of international meetings. In particular, the seventeenth principle of the Rio Declaration on Environment and Development (1992) is devoted to the creation of processes for environmental impact assessments by governments around the world.

THE ENVIRONMENTAL IMPACT STATEMENT PROCESS

Most environmental impact assessments follow a process similar to the one mandated for the EIS, in which a lead agency collects and assimilates all the environmental information required for the EIS (Sullivan 2003). The first step in the process is to determine whether a complete EIS is required. When there is likely to be little impact, the lead agency can write an environmental assessment (EA), which is much simpler. In the late 1980s agencies annually prepared only 450 complete environmental impact statements, compared to an average of 15,000 environmental assessments (Gilpin 1995).

The first element of the actual EIS is scoping, where the lead agency identifies key issues and concerns of interested parties. A notice of the intent to conduct an EIS is published in the Federal Register and is sent to all potentially interested parties. Usually, the agency releases a draft environmental impact statement (DEIS) for comment. After interested parties and the general public have had the opportunity to comment on the draft, the agency releases the final environmental impact statement (FEIS).

In some instances, usually as the result of litigation or the availability of new information, the agency later releases a supplemental environmental impact statement (SEIS). Once all the protests are resolved the agency issues a record of decision, which is its final action prior to implementation.

The Council on Environmental Quality (CEQ), also mandated by the NEPA, sets the regulations that outline the format for the actual EIS. They mandate that an EIS should contain the impact of the proposed action, any adverse environmental effects that cannot be avoided, any possible alternatives to the proposed action, and any irreversible commitments of resources that the action would require if it were implemented. All mitigation measures to address identified harms must also be included in the EIS. Throughout the EIS process, the public must have opportunities for participation (Sullivan 2003). In 1994 President Bill Clinton issued an executive order adding environmental justice issues to the EIS process.

PROBLEMS WITH ENVIRONMENTAL IMPACT ASSESSMENTS

One of the problems with environmental impact assessments is that in many cases, after the factors have been analyzed, there is little to force the actors to change their decisions. Once the EIA is complete, the action can go forward regardless of any negative environmental consequences. In the case of the EIS, the NEPA provides no enforcement provisions, though various court decisions have held that an EIS must be done and that it should be used to inform decision makers of potential environmental problems. However, at present nothing requires planners to change their decisions based on an EIS’s findings, nor is there any penalty for ignoring an EIS. In the early 1970s groups trying to stop an action used EISes to initiate numerous lawsuits. At the end of the 1970s the U.S. Supreme Court in Vermont Yankee v. NRDC (1978) reversed two district court decisions remanding the NRC for not addressing environmental issues adequately in their EIS. This decision limited the ability of district courts to reverse agency decisions (Vig and Kraft 2000). By the end of the 1980s the federal courts consistently declined to hear lawsuits on environmental issues if the EISes were properly done. According to the courts, planners may elect to include or exclude EIS findings from their projects, and if they choose to ignore it, others have a right to bring pressure on them. The CEQ cannot stop an action, but it can delay it by requesting further reassessment.

Another problem with the creation of EIAs springs from the uncertainty surrounding some situations. Uncertainty may come from a lack of scientific under-
standing of an issue or from the nature of the information required. The issues may be extremely complex, or may deal with timescales that create potential problems for understanding the issue. For example, the proposed nuclear waste facility at Yucca Mountain, Nevada requires the consideration of environmental changes at the site over a 10,000-year period. The Yucca Mountain case also provides an example of another problem—the quality of the information used in creating an EIS. It was discovered that the researchers doing the assessment at Yucca Mountain manufactured some of the information they used for the EIS; a subsequent government study ruled that even though the data was suspect, the overall decision based on it was sound (Department of Energy 2006). For some governments around the world, the lack of resources and skilled personnel create problems for producing a quality EIA.

This is not to say that identifying environmental issues has no effect on the decision-making process. A number of studies have shown that EISes force greater environmental awareness and more careful planning by federal agencies (Vig and Kraft 2000). The very fact that the information exists means it plays a role. The EIS is circulated among state, local, and federal agencies and the public. Because of this circulation, the EIS can become an early warning system for environmental groups, alerting them of potential issues for their consideration (Rosenbaum 2005). The identification of potential problems has motivated public support against actions and led to rethinking of initial plans. Having the information is better than not having information, even though it may not be used.

ENVIRONMENTAL KUZNETS CURVES

Casual observation suggests that cities in newly industrialized countries such as Bangkok, Beijing, Calcutta, and Mexico City are more polluted today than they were twenty to thirty years ago, while cities in older industrial countries such as New York, Tokyo, and London are cleaner than they were twenty to thirty years ago. This apparent paradox raises the question of whether higher income levels result in a better or worse environment. The environmental Kuznets curve (EKC) hypothesis proposes that there is an inverted U-shaped relationship between various indicators of environmental degradation and income per capita. This became known as the environmental Kuznets curve because of its similarity with the shape of the income-inequality relationship discovered earlier by Russian-American economist Simon Kuznets.

THE EKC AND ENVIRONMENTAL DEGRADATION

This relationship was discovered by Gene Grossman and Alan Kreuger in the early 1990s. They found that at low levels of per-capita income, concentrations of sulphur dioxide, suspended particulate matter, and water pollutants increase as income increases. However, once per-capita income reaches a particular threshold, concentrations of these pollutants decrease as income continues to rise.

The emissions studied by Grossman and Kreuger have local or own-country pollution effects and relatively low abatement costs. Global pollutants such as greenhouse gases represent a second important type of environmental degradation. A 1995 study by Douglas Holtz-Eakin and Thomas Selden examined emissions of carbon dioxide, which is a global pollutant. Their analysis reveals that the emissions continue to rise with income, a finding that is not consistent with the EKC.

Deforestation is a third important type of environmental degradation. Economic development is generally expected to reduce a nation’s agricultural sector and increase its industrial sector. Such development is also associated with the use of modern agricultural technology, which reduces land requirements. Logging and the demand for wood as an energy source is likely to grow as a country develops, but this demand may wane as industrialization takes over.

In their 1994 study, Maureen Cropper and Charles Griffiths examined the EKC shape for deforestation. The overall result was a hump-shaped relation between per-capita income and deforestation. The income at which the rates of deforestation peak is very high. Although it is reassuring that the rates of deforestation level off at suffi-
iciently high per-capita income levels, the major damage to the environment occurs before these income levels are reached.

**FACTORS AFFECTING THE INCOME-ENVIRONMENT RELATIONSHIP**

Having looked at three varieties of environmental degradation, it is necessary to recognize that the environmental quality is the outcome of the interplay of emissions and abatement (or depletion and regeneration in the case of renewable resources). The income-environment relationship captured by simple regression exercises cannot distinguish between the demand side and supply side forces that drive this relation. Income acts as a surrogate for a variety of underlying influences. Grossman and Kreuger provide an intuitive explanation of these influences, as outlined below.

**The Scale of the Economic Activity** A larger scale of economic activity per unit of area, all else being equal, results in increased levels of resource use and waste generation. Here, income acts as an indicator of economic activity, encouraging a positive relation between environmental degradation and income.

**The Composition of the Economic Activity** Different sectors of the economy have differential pollution and resource use intensities. Industry, especially manufacturing, tends to be more pollution intensive than either agriculture or services. The share of industry in a nation’s gross domestic product (GDP) first rises with economic growth and then declines as the country moves from the preindustrial to the postindustrial stage of development. This influence encourages an inverted U-shaped relationship between environmental pollution and income level.

**The Technique Effect** At low income levels, people are more concerned with their food and other material needs and less concerned with environmental quality. At higher income levels, people begin to demand higher levels of environmental quality to go with their increased prosperity. On the supply side, low incomes mean that countries and individuals cannot afford much expenditure on pollution abatement, even if the demand were there. Economic growth not only creates the demand for improved environmental quality, it also makes resources available to supply it, resulting in cleaner technologies. Stripped of the scale and composition effects, the technique effect predicts that environmental degradation would decline as per capita income increases.

The sum of all these effects defines the observed income-environment relationship. For example, in the case of global pollutants, the technique effect is weak because a disciplining of domestic production would not benefit domestic consumers, who therefore do not demand cleaner techniques of production. For economies that experience growth later than the developed
economies, it is possible that they will continue to produce industrial goods not only for their own use, but also for their trading partners. In these economies, the composition effect that is relevant for developed nations that have moved beyond the industrial phase does not apply. This reduces the possibility of a decrease in environmental degradation at higher incomes. Hence, more than the actual shape of the EKC, it is the lessons learned from analyzing it that are important in understanding the relation between per capita income and environmental degradation.

EPISTEMOLOGY

Any systematic exposition of the grounds of and means to knowledge constitutes an epistemology. Standard epistemologies of mathematics find such grounds in axiomatic self-evidence and means in methods of proof. Epistemologies of the natural sciences additionally underscore methods of experimental verification. Emerging in the shadow of the natural sciences, the social sciences have since their inception been the province of a stubborn epistemological divide. On the one side are those who insist that the natural sciences offer the only valid model of the attainment of knowledge about the empirical world and that the social sciences should thus strive to emulate their methodological precedent. On the other side are those who insist that human actions and creations are different in kind from the events and objects to which natural scientists attend and require methods of approach and comprehension entirely their own. Strictly speaking, these alternatives are incompatible; no perfect compromise is possible.

Emerging clearly in the middle of the nineteenth century, the divide at issue rests in distinct philosophical precedents and traditions of scholarship. On the side of a unified science is Auguste Comte’s “positivism,” which casts society as the final and most complex object to become available to the senses in the course of the evolution of human cognition and amenable, if not precisely to experimental manipulation, then to controlled comparative inquiry rigorous enough to yield knowledge in its wake. Comte’s Course of Positive Philosophy (1830–1842) inaugurates what he coined “sociology” as a science every bit as natural as its predecessors, but clearly reflects both the rationalism of René Descartes and the empiricism of Etienne Bonnot de Condillac. Comte’s most influential epistemological heir is Émile Durkheim, who takes particular pains to distinguish the empirical domain of psychology from that of sociology in his late nineteenth-century work. The former encompasses at once what is common to all human beings and what is idiosyncratic to one or another of them. The latter, encompassing what marks human beings as members of specific collectivities, is the proper domain of “social facts” available to the senses first of all as the experience of externally imposed obligation or coercion. It yields the classic definition of society as a “normative order.” It permits two basic modes of inquiry, both of which might be put into the service of controlled comparison. One of these pursues a sampling of particular cases substantial enough to reveal patterning variables and their statistical co-variations. Another seeks to extract from perhaps only a single case a model of the system of which it is representative or expresses the limit. The first is the mode of statistical and quantitative inquiry not only in sociology but across all the social sciences. The second is the mode of model-theoretic inquiry—whether rigorously algebraic, as in much of contemporary economics, or largely qualitative, as in Durkheim’s own Elementary Forms of the Religious Life (1912).

On the side of the divide itself is Wilhelm Dilthey’s programmatic distinction between the natural sciences and what he termed the Geisteswissenschaften, sciences of “spirit” or “mind” or “human sciences.” The latter cate...
Epistemology

... category includes all of the disciplines that make up the social sciences, but its cardinal focus is the discipline of historical inquiry and what would come by the late nineteenth century to be known as cultural anthropology. The human sciences do not in Dilthey's typology produce “knowledge” but instead produce “understanding.” The latter is a mode of knowing grounded of necessity in self-reflection because the objectifications of spirit or mind—human actions and artifacts—that constitute its investigative terrain are precisely the objectifications of such psychic states as intentions, beliefs, values and sentiments. The human scientist understands any such objectification not in determining its efficient cause but in interpreting its always particular “meaning” or “significance” in light of the broader historical or cultural context in which it is embedded. Dilthey's work follows the founder of biblical hermeneutics, Friedrich Schleiermacher, in presuming that the process of interpretation rests essentially in the interpreter’s capacity imaginatively and empathetically to enter into the lives of others. He derived his thoroughgoing separation of the physical from the experiential world from Immanuel Kant's similarly thorough separation of the objective from the subjective in his three Critiques, published in 1781, 1788, and 1790. In his appropriation of Kant at least, Dilthey is at one with his only slightly later contemporary, Max Weber.

Weber is well known for his address of the “problem of objectivity” in the human sciences. He recognized that particular evaluative commitments do and even should influence the content of the questions that the human scientist poses. He insisted that the scientist’s research, properly conducted, should and can produce nothing else but facts. His resolution still has its adherents, but the problem of objectivity itself long predates him and lasts beyond him. In its general form, it is the result of the reflective recognition that beliefs and evaluative orientations are generally conditioned by or contingent upon their historical, cultural and social context; hence, for example, Thorstein Veblen's observation that distinct fractions of the dominant classes are drawn to those intellectual pursuits that are most intimately concerned with the practical bases of their dominance. Prima facie, the same should broadly be true of beliefs about and evaluative orientations toward the historical, the cultural and the social themselves. This does not entail that the latter beliefs and orientations are wrong-headed, but it does point to the need for an account of how and when and why a researcher is right to suppose that they are enduringly true or valid. Thus construed, the problem of objectivity has inspired three general responses. One is Comte’s own: a positivist rendering of cognitive and moral evolution positing that modern society has become disburdened of the sources of the errors and confusions that clouded the mental and moral landscapes of societies less developed. Though no longer with a positivist inflection, a similar evolutionism has a central place in Jürgen Habermas’ much more recent efforts to reestablish the foundations of a critical social theory. A second response emerges in the later Marxist tradition, in which the problem of objectivity gains intensity with the presumption that the prevailing ideas of every class-divided society are ideological distortions that serve not truth but the reproduction of the dominant class.

Though with many variations, it seeks in social institutions or psychosocial circumstances those factors that permit certain individuals to become detached from their classes of origin and so think outside of the boundaries that would otherwise constrict their judgment. In a classic contribution to what is thus a “sociology of knowledge,” Karl Mannheim’s work sees such factors in the coalescence of the secular, liberal university in late eighteenth- and early nineteenth-century Europe. Louis Althusser’s work focuses instead on the conjunctures of politico-economic structure and personal circumstance in which an investigator’s exercise of experiment and critique effect an “epistemic break” from the ideology in which his thinking had previously been mired. Though once again with many variations, a third response might be called pragmatic. The philosophical resources it taps include Kant and Ludwig Wittgenstein. From Weber to anthropologist Clifford Geertz and social theorist Niklas Luhmann, its proponents regard proper intellectual labor in the human sciences as having its end in heuristic and diagnostic constructions and interventions that, whatever their contingencies or motivations, facilitate clarity, communication and translation. Hardly a return to positivism, this response nevertheless highlights the analytical service of an intellectual device of steadily increasing saliency in the epistemological toolkit of the natural sciences themselves: the model.

Equal Opportunity

EQUAL OPPORTUNITY

The term equal opportunity refers to the absence of discrimination based on involuntary personal attributes, such as sex, racial or ethnic origin, religion or belief, disability, age, or sexual orientation. The concept of equality of opportunity identifies equality with open and fair competition for scarce resources but does not challenge an inequalitarian distribution of resources within society. This has sparked disagreement in political and theoretical struggles over what constitutes a “just society.”

FORMAL EQUALITY OF OPPORTUNITY

The notion of formal equality of opportunity requires that positions, offices, and admissions in society are open to all applicants and that formal procedures are used to select candidates based on qualifications deemed relevant to successful performance in a position or program. Individual abilities and ambition are valued as criteria while factors derived from group identities assigned by birth or social class, such as race, family, caste, religion, are excluded. Equality of opportunity carries with it the promise of upward social and economic mobility due to the removal of legally protected rights and privileges for particular classes or groups. Equality of opportunity emphasizes procedural and legal means of providing equal access to social goods, in contrast to alternative approaches to equality; for example, equality of outcomes, equality of resources, and democratic equality.

Equality of opportunity assumes that it is unfair if factors beyond the control of an individual significantly shape a person's chances in life. Formal equality of opportunity can be justified as an enhancement of individual life chances as well as a means for maximizing the well-being of society. Proponents of equality of opportunity associate it with a meritocratic system in which the most talented and ambitious are the most rewarded regardless of socioeconomic background.

LIMITATIONS OF FORMAL EQUALITY OF OPPORTUNITY

A central challenge to the very concept of formal equality of opportunity is that it does not take into consideration how circumstances beyond the control of an individual influence the ability to compete for scarce resources. In the case of standardized tests to evaluate a student's educational and professional potential, such as the Scholastic Aptitude Test (SAT) in the United States, formal equality of opportunity requires students to take the test under the same conditions and use the final test score as a measure to evaluate students' performance. It thereby disregards the access some students have to more economic and edu-

EQUAL EMPLOYMENT OPPORTUNITY COMMISSION
SEE Integration.
A narrow perception of equality of opportunity is not inherently incompatible with profiling or statistical discrimination, which uses group characteristics such as gender, ethnicity, or age as a proxy for productivity in hiring and promotion. Profiling occurs when statistical trends are used to justify associating negative attributes with members of a group, such as a high crime rate, or risks associated with a particular phase in the life course like having children. These group characteristics are used as indicators for current and future productivity, thereby compromising the notion of equality that calls for an evaluation of each applicant on its own merits.

Equality of opportunity has historically been confined to the public sphere, neglecting the sources of inequality identified with areas traditionally held as private, such as family, marriage, and religion. Opening up all sectors of employment to women, for example, does not offer them equal opportunity for advancement when employers deny them (paid) pregnancy leave. While all workers may be subject to identical rules, women are disproportionately adversely affected. Formal equality of opportunity does not seek to change the social, economic, and cultural forces that structure the division of labor along gender, race, and class lines. Rather than resolving the question of equality, a larger degree of formal equality often reveals the impact of socioeconomic inequality within society.

SUBSTANTIVE EQUALITY OF OPPORTUNITY

Substantive equality of opportunity takes the broader social situation into consideration in determining criteria for qualification and performance. The appropriate means for achieving substantive equality of opportunity are often controversial. One possibility for achieving substantive equality of opportunity is affirmative action. The challenges of affirmative action in theory and practice are illustrated in the reform of the admissions system of the Indian Institutes of Technologies (IITs), French elite universities, and higher education in the United States.

Indian Institutes of Technology were founded in 1951 and became a leading institution in professional training in India. Entrance is based on a standardized test without consideration of socioeconomic status and is granted to approximately 2 percent of the applicants. Despite the formal neutrality of the test, the vast majority of students admitted come from the urban middle class with access to good schools and the resources to attend costly preparatory courses. To further substantive equality of opportunity IITs were required to reserve 22.5 percent of seats for students of historically disadvantaged schedule castes and tribes in 1973. Reserved seats were awarded to candidates scoring at least 66 percent of the score of the lowest admitted applicant in the general test or to candidates successfully completing a one-year preparatory course. Despite these lower admission standards not all reserved seats are filled pointing to the challenge of opening elite educational institutions to low-income students without further counterbalancing vast power and wealth disparities in Indian society (Murati 2003).

France’s elite universities also use highly competitive standardized exams for admission. The vast majority of students performing well on these tests have attended very selective preparatory schools that rarely admit working class or immigrant students. In 2001 Sciences Po, one of these universities, began a special entrance program that admits a limited number of students from designated zones in impoverished suburbs. Relying on geographic criteria rather than socioeconomic status or ethnicity, the program does not directly challenge “republican values” that hold the French republic to be indivisible and all citizens to share equally in a common civic culture. While in practice the program admits many first- and second-generation immigrants from Morocco and Algeria their ethnicity is not officially taken into consideration, thereby avoiding discrimination between citizens or delineating the separate communities within France.

In the United States President Lyndon Johnson introduced affirmative action as a method of redressing the legacy of racial discrimination in 1965. Affirmative action programs in education and training were brought before the Supreme Court in the 1970s. In Bakke v. Regents of the University of California (1978) the Supreme Court struck down a medical school’s affirmative action program that set aside sixteen seats for consideration by a separate admissions committee but the court upheld the legality of affirmative action per se. In 2003 the Supreme Court upheld affirmative action in higher education ruling that race can be one of many factors considered for college admission (Gratz v. Bollinger and Grutter v. Bollinger [2003]). Affirmative is no longer justified on the basis of redressing past oppressions and injustice but in terms of a “compelling state interest” in diversity at all levels of society.

These three examples show that substantive equality can be furthered through very different affirmative action programs posing different kinds of challenges. India relies on reserved seats while the United States dismissed such quotas as unconstitutional. The United States uses race as one of many factors in evaluating an application while France dismisses affirmative action based on socioeconomic and ethnic status as running counter to its republican values. France, while not having a formal affirmative
action policy in higher education, is currently experimenting with geographically based programs. The political struggle over substantive equality of opportunity is inseparable from the normative question, what makes institutions legitimate? As Xavier Brunschvicg, the Science Po’s director of communication explains: “We believe, here, that we are creating the elite of French society. But in order for these elites to be accepted, they have to be legitimate. Reproduction is not legitimate. We need to diversify to be legitimate, to help the egalité des chances [equality of opportunity] along” (Conley 2003). Pursuing substantive equality of opportunity redresses many of the limitations of formal equality, but it cannot resolve the question of why so many must compete for so little.

JUSTICE AND EQUALITY OF OPPORTUNITY

Is equality of opportunity the most basic formulation of equality, or merely one type of equality among others? In his theory of justice as "fairness," John Rawls argues that equality of opportunity must be combined with a redistribution of social goods. Rawls incorporates both formal and substantive forms of equality of opportunity into his theory of a just society through his second principle of justice, which holds that "Social and economic inequalities are to be arranged so that they are both (a) to the greatest benefit of the least advantaged [the “difference principle”] and (b) attached to offices and positions open to all under conditions of fair equality of opportunity" (Rawls 1971, p. 83). Rawls argues that even without formal barriers to equality, those with greater social and natural advantages, for example intelligence and strength, will get a disproportionate percentage of social goods like income and positions. These advantages are beyond an individual’s control and thus the unequal outcomes are unjust.

Rawls’s theory of fair equality of opportunity requires that resources be redistributed across social classes. In order to give every individual the same opportunity to cultivate his or her abilities and pursue his or her ambitions, the state must provide additional resources, for example bilingual education or health care, when individual families are unable to provide them. No amount of substantive equality of opportunity, however, will eliminate all socioeconomic and natural inequality. Consequently, Rawls argues that equal opportunity requires the addition of the “difference principle.” By restricting the unequal distribution of goods to the benefit of the least advantaged, the difference principle requires that the rewards gained from individual talents benefit society as a whole and not solely the individual who possesses them.

In contrast to Rawls, there are many who question whether equality of opportunity is compatible with alternative conceptions of equality. John Schaar criticizes the idea that equality of opportunity is a basic definition of equality because it “really only defends the equal right to become unequal by competing against one’s fellows” (Schaar 1967, p. 241). He rejects the supposed neutrality of equality of opportunity and emphasizes its underlying individualistic competitive ethic. As Schaar contends, equality of opportunity reinforces particular social values to the exclusion of others and rewards only those with talents that conform to these values.

Robert Nozick (1974) embraces this individualistic competitive ethic in his libertarian approach and argues that the equality of opportunity Rawls endorses is undermined by the difference principle. Nozick’s “entitlement theory” insists that only the process by which goods are acquired is relevant for a just distribution. He thus rules out redistributive approaches to equality like Rawls’s that consider equality of outcome as well as procedures.

Michael Walzer (1983) concurs with Schaar as well as many communitarians that there is no single, universal standard for what constitutes an egalitarian society. Equality of opportunity is one principle of just distribution among others, each of which expresses a particular set of social values. These alternative conceptions are not necessarily compatible and compete for priority within a particular society. Walzer argues for a “complex equality” approach that maintains a plurality of distributive principles in light of the diverse range of social goods and actors in any society.

Feminist theorists question Rawls’s basic assumption, shared by many in equality of opportunity debates, that equality must be based on qualities that are shared by all and that certain kinds of difference (such as sex, race, sexual orientation, and religion) should not be taken into consideration. Universal standards like Rawls’s theory of justice often assume values and characteristics that are drawn from more privileged members of society. Susan Okin (1989) shows how Rawls’s theory of justice depends on the family, but does not sufficiently address whether relationships within the family are equal. Iris Young (1990) argues that forms of inequality are not limited to material resources, such as wealth, income, and positions that can be redistributed among members of society. Evaluating equality of opportunity also requires an analysis of the particular social structures (i.e., decision-making procedures, the division of labor, and culture) in which opportunities can be realized.

The debate over equality of opportunity opens onto core political and theoretical questions, including the delineation of public and private domains, individual versus group identity, and the possibility of impartial standards. At stake in this debate are shared concerns with legitimating and transforming political institutions, nego-
tiating competing social values, and cultivating practices of social justice.

EQUAL PROTECTION

*Equal protection* as a legal concept is the idea that individuals should be treated in the same manner as other individuals in similar circumstances. The Equal Protection Clause of the Fourteenth Amendment to the U.S. Constitution provides that “no state shall … deny to any person within its jurisdiction the equal protection of the laws.” According to the U.S. Supreme Court, the Due Process Clause of the Fifth Amendment also has an “equal protection component,” protecting against arbitrary or unreasonable discrimination by the federal government.

Adopted during the five years following the Civil War, the Thirteenth, Fourteenth, and Fifteenth Amendments abolished slavery, extended U.S. citizenship to slaves and descendants of former slaves, ensured the right to vote regardless of race, and gave Congress the power to enforce these guarantees through legislation. In that context, the Fourteenth Amendment’s Equal Protection Clause was intended to provide equal rights for blacks, and that was the view taken by the U.S. Supreme Court in the first case in which the clause was invoked. According to the Court in the *Slaughterhouse Cases* (1873), the purpose of the Equal Protection Clause was to protect “Negroes as a class” from discrimination “on account of their race.”

In subsequent decisions, however, the U.S. Supreme Court limited both the scope and the substance of the Constitution’s equal protection guarantee. In the *Civil Rights Cases* (1883), the Court ruled that Congress’s authority to enforce the Fourteenth Amendment applied only to government actors, not private individuals. Thus, Congress could not use its enforcement power to prohibit racial discrimination in places such as hotels, restaurants, and theaters. And in *Plessy v. Ferguson* (1897), the Court
held that state laws requiring “equal but separate” facilities for blacks and whites did not violate the Equal Protection Clause, because the Fourteenth Amendment guaranteed political equality but not social equality. According to the Plessy Court, denying blacks the right to serve on juries deprived them of equal protection of the laws, but maintaining dual school systems for black and white students did not. With these decisions, the Supreme Court gave constitutional sanction to racial segregation in education, transportation, public accommodations, employment, and housing.

The Plessy Court cited the maintenance of dual school systems as an example of a policy that was consistent with the separate but equal doctrine. It is noteworthy, then, that it was in a case involving segregated schools that the Court later overturned Plessy v. Ferguson and its approach to equal protection. The Supreme Court’s decision in Brown v. Board of Education (1954) was the culmination of a twenty-year litigation campaign led by the National Association for the Advancement of Colored People to eradicate the separate but equal doctrine in public education. Throughout the 1930s and 1940s the NAACP had brought cases to the Court, seeking to enforce equality between schools for black and white students. By 1954, in the cases that comprised Brown v. Board of Education, the organization was poised to challenge segregated education itself, and the Supreme Court was prepared to agree. In Brown, the Court ruled that “in the field of public education, the doctrine of separate but equal has no place. Separate educational facilities are inherently unequal.”

The Brown Court explicitly limited its rejection of segregation to public education, but the decision gave momentum to the nascent civil rights movement that would highlight racial inequality in the United States and motivate political change. One of the early events of the movement was the Montgomery bus boycott of 1955 and 1956. The boycott ended when, in Gayle v. Browder (1956), the U.S. Supreme Court struck down the ordinance requiring segregated seating on city buses as a violation of equal protection of the laws. In other decisions, the Court rejected segregation in public facilities such as courthouses, parks, beaches, and golf courses.

Because the Fifth and Fourteenth Amendments did not prohibit discrimination by private actors, segregation persisted in interstate transportation, public accommodations, employment, and housing. But in Boynton v. Virginia (1960), the Supreme Court ruled that Congress could use its power to regulate interstate commerce to bar discrimination in interstate transportation, and with the Civil Rights Act of 1964, Congress used the commerce power to prohibit discrimination in public accommodations and employment as well. Spurred by the sit-ins of the early 1960s, in which nearly 75,000 demonstrators were involved, the passage of Title II of the Civil Rights Act guaranteed equal access to restaurants, hotels, and places of entertainment that operated in or affected interstate commerce. Title VII, as the Supreme Court interpreted it in Griggs v. Duke Power Company (1971), proscribed “not only overt discrimination” in employment, but also employment policies that were “fair in form but discriminatory in practice.” Four years later, Congress passed Title VIII of the Civil Rights Act of 1968. Known as the Fair Housing Act, the law forbade discrimination in the sale, rental, and financing of housing.

Although the Supreme Court initially ruled that the Equal Protection Clause of the Fourteenth Amendment was intended to guarantee equal rights for blacks, the Court later adopted an expansive interpretation of the “persons” to whom equal protection was guaranteed by the clause, even recognizing corporations as persons. But after 1938, discriminatory treatment by the government based on race would be more difficult to justify than other types of discrimination. Following on Justice Harlan Stone’s famous footnote in United States v. Carolene Products (1938) in which he suggested that “prejudice against discrete and insular minorities” called for “more searching judicial inquiry,” the Supreme Court developed a three-tier approach to equal protection claims. In this approach, government classifications based on race are “suspect” classifications to which “strict scrutiny” must be applied. Strict scrutiny requires government to prove that making distinctions based on race is the least restrictive means available to achieve a compelling interest. Since 1976, sex-based classifications have been identified as “quasi-suspect” and entitled to intermediate or heightened judicial scrutiny. Under “intermediate scrutiny,” a policy that categorizes individuals based on sex must be substantially related to an important government interest. Regarding all other bases for discrimination, the Court requires that the discrimination be reasonably related to a legitimate governmental objective.

EQUALITY

Equality is a highly complex concept, there being as many forms of equality as there are ways of comparing the conditions of human existence. Equality can refer to numerous features of human life, which is why the term is usually preceded by an adjective that specifies which one is captured, such as social equality, legal equality, political equality, formal equality, or racial equality, to mention but a few. This entry will focus on the more important variants.

THE STRUGGLE FOR EQUALITY

There is, firstly, political or legal equality, which is concerned with the right to vote, to stand for office, and to be treated equally before the law, irrespective of gender, race, religion, age, disability, social background, or other such features. In medieval times, rulers took it for granted that hierarchy is natural and inevitable and that a few are entitled to privileges denied to the many. One of the achievements of the Enlightenment in the eighteenth century was the acknowledgement that all human beings have equal moral worth by virtue of a shared human essence. The Declaration of Independence ("All men are created equal") and the Declaration of the Rights of Man and Citizen ("Men are born and remain free and equal in rights") enshrined this principle in the national constitutions of the United States and France, respectively.

Numerous privileges of rank and order that had survived from feudal times were abolished in the following centuries: Slavery was done away with, universal suffrage was introduced, public offices were opened up to competition, and racial segregation was replaced with racial integration. Not everyone has been content with these achievements, however, and many today demand further changes, particularly with regard to race relations, gender equality in the workplace, and the rights of the disabled.

While the struggles over legal and political equality continue, the academic discourse in the social sciences has been concerned more with another type of equality, namely, that of substantive equality.

SUBSTANTIVE EQUALITY

Political thinkers started to question the worth of the principle of political or legal equality, given that, if left on its own, it merely grants each person an equal right to eat in an expensive restaurant—in the sense that no one is excluded on the grounds of race, gender, or religion—but entirely fails to address individuals’ capacity to exercise that right, that is, their money. If wealth or some other measure of welfare is a prerequisite for exercising rights to equal treatment in other spheres, the question arises as to how social goods should be distributed. Once this normative issue is settled within political philosophy, the related practical question in public policy becomes imminent as to whether, how, and to what extent liberal democracies should ensure a level of substantive equality.

While many issues surrounding this question remain contentious, others are now regarded as relatively uncontroversial. Figure 1 depicts some of the more important debates carried out in political philosophy in recent decades. Once substantive equality is agreed upon as an aim worth pursuing, it is necessary to specify if equality is seen as an instrumental or intrinsic ideal. A wide consensus in favor of the latter has emerged, which states that equality is a good thing because of its implications for values other than equality itself, such as greater individual choice, personal autonomy, or the capacity to exercise rights. Hence, the desirability of a more equal distribution is due, not to the fact that it is more equal but that it is expected to promote that other value. Inequality can therefore be acceptable, provided a so-called Pareto improvement is achieved so that at least one person has been made better off without making anyone else worse off.

On the next level, the concept of equality requires a further distinction between individual features that result from voluntary choices and those that are a product of social and natural circumstances. The majority of egalitarian philosophers claim that it is unfair if, to employ a term coined by John Rawls (1921–2002), “morally arbitrary factors” differentially influence the course of people’s lives, and that redistribution is justified as a way of neutralizing them (1971). The fundamental aim of equality should be to compensate people for undeserved bad luck, for aspects of their situations for which they are not responsible. As Ronald Dworkin states (2000), there is a moral warrant to level the inequalities in the distribution of social goods that are generated by differing endowments, while leaving intact those inequalities generated by differential effort,

planning, and risk taking. No one deserves their genetic endowments or other accidents of birth, such as who their parents are and where they were born. The advantages that flow from those blessed with such fortunes must not be retained exclusively by them.

This is the stage where the traces of consensus in political philosophy end, as much work in the discipline has been dedicated unsuccessfully to the subsequent question as to what it is that is to be equalized. The aim has been to establish the appropriate standard of interpersonal comparison, or “currency” of egalitarian justice. Several suggestions have been made. Rawls proposes what he calls “primary goods”: income, wealth, opportunity, and the bases of self respect. Nobel laureate Amartya Sen concentrates on “capabilities” to choose between various “functionings” that a person is able to realize in his or her life. Further accounts are G. A. Cohen’s “access to advantage” and Dworkin’s “resources.”

The diversity of these proposals shows how difficult it is to assess the features of an individual’s conditions that are to be rendered equal: They all have different causes and require compensation in a different way. Should we follow proposals that ensure an equal end-state outcome? Or should we guarantee equality achieved at some initial point in time, irrespective of what level of equality is achieved thereafter?

While the debate in political philosophy is ongoing, substantive equality is a more imminent concern for political practice, where policymakers in liberal democracies face pressures from their electorates if they fail to take measures that ensure equal life prospects to some degree.

Historically, the welfare state has been the vehicle through which governments have sought to address the problem. Social and economic security has been provided to the state’s population by means of pensions, social security benefits, free health care, and so forth. However, increasing pressures of globalization toward the end of the twentieth century compelled welfare states to subject their public expenditures to much more stringent economic scrutiny. Public spending and taxes were cut and responsibility for welfare was reassigned from the state to the individual. States have done so to varying degrees, however, and the measurable levels of equality today differ markedly as a result.

MEASURING EQUALITY

When complex social phenomena are condensed into a single measure, criticism is bound to arise. Even so, the most common statistical index in the social sciences to measure substantive equality within a society is the so-called Gini-coefficient, named after the Italian statistician Corrado Gini (1884–1965). The Gini-coefficient (Figure 2) varies between the limits of 0 (perfect equality) and 1 (perfect inequality) and is best captured visually with the help of a diagram that measures the percentage share of the population on the x axis and the percentage income distribution on the y axis. The coefficient represents the geometrical divergence of the so-called Lorenz curve, which measures the actual percentage income distribution, from a line with a 45-degree angle, which represents perfect equality, in the sense that everyone is equally
wealthy. The closer the Lorenz curve is to the diagonal line, the smaller the shaded area beneath that line, and the smaller the resultant Gini-coefficient, the more equal is the society's income distribution.

During the 1980s and 1990s, some advanced industrial nations experienced significant shifts in this coefficient, most notably the United Kingdom and the United States, where the neoliberal economic policies introduced by the governments of the day brought about notable increases in income inequality. As statistics produced by the United Nations show (UNDP 2005), in the United Kingdom the Gini-coefficient rose from 0.25 in 1979 to 0.35 in 2000, while the United States saw an increase from 0.36 to 0.43 over the same period. By comparison, countries with more extensive welfare state arrangements, such as most Scandinavian countries, have experienced only minor changes and continue to record Gini-coefficients of between 0.24 and 0.26. On the other end of the spectrum, states such as Brazil, Mexico, and, increasingly, China report the highest income inequality, with coefficients of between 0.47 and 0.60.

EQUILIBRIUM IN ECONOMICS
The concept of an economy in equilibrium is pervasive in modern economics. The modern neoclassical concept has been a central tenet of economics since the late nineteenth century when economists began importing notions from physics and mechanics. The idea imported from physics is that claiming an economy is in a state of equilibrium implies forces exist that would correct any accidental deviation from that state of equilibrium. As such, equilibrium is a dynamic concept as it involves constant corrective movement, movement that is always in the direction of restoring an equilibrium state whenever perturbed by frequent, possibly random, deviations. An equilibrium can be dynamic in another sense, such as when it represents a persistent pattern even though the objects that form the pattern may be in constant movement. The obvious physics example is the solar system with the planets in constant movement but in predictable and stable patterns. Similarly, one can think of an entire economy in a “stationary state” with constant flows of goods and services that year by year maintain a stationary equilibrium pattern (i.e., no growth or decay).

The classical school of the early nineteenth century advanced a notion of an equilibrium that was invested mostly in the static outcome of exhausting all possibilities of improvement. Typical examples were the improvements realized by an individual firm’s progressive division of labor or by a firm’s choice to switch industries to one where the rate of return on investment capital is higher. The individual firm was said to be in equilibrium only when its production process cannot be further divided. Industries in an economy were said to be in equilibrium only when all firms in all industries are earning exactly the same rate of return and hence there would be no possibility of gain by switching industries. In both cases, the state of equilibrium depends on whether the firm knows of any possibility of improvement. It is always possible that the necessary condition for equilibrium—such as the uniform rate of return—is not actually fulfilled because firms are either unaware of any possibility of improvement or are in some way constrained from moving to a more profitable industry (as would have been the case in the eighteenth century when the king granted a profitable monopoly to one producer).

For the most part, given the diverse history of the concept, economists and economics textbooks seem confused about just what equilibrium means. Is it a static balance such as when a market’s supply equals demand? Or is it a singular state of affairs in a dynamic system that explains how the balance was obtained? A balance can be static but an equilibrium is always a dynamical concept. When modern economists say that an economy is in equilibrium they seem to be saying only that the operative forces in the economy are in balance as there is rarely anything said about the explicit dynamics needed to restore or obtain the equilibrium.
In the case of a market where supply and demand are in balance, what is most important is that there can be only one going price: the one price that clears the market and thus the one price at which it is possible for every participant to be maximizing. And while the classical economists were interested in a state of affairs where there would no longer be a reason to change as there is no possibility of gain, the primary purpose for the neoclassicals' assumption of a state of equilibrium is to obtain the state of affairs where everyone is knowingly maximizing. It is primarily the mathematics of universal maximization that characterizes modern economic theory since the late 1930s.

EQUILIBRIUM AS A PROBLEM FOR MATHEMATICAL ANALYSIS

The beginning of neoclassical attempts to incorporate explicit equilibrium concepts in economics in the late nineteenth century was coupled with the attempts to make economics a mathematical science like physics. The main methodological question was whether one could build a mathematical model of a whole economy consisting of many independent decision makers guided by prices determined in various markets such that the model would imply the existence of a unique set of prices (one price for each good or service transacted in the economy). One of the first economists to attempt this in the nineteenth century was the French economist Léon Walras. His approach was to represent all participants in the economy (producers or consumers of goods and services) with their objective functions (i.e., their respective utility or production functions), which represent what they wish to maximize. Each individual was simply assumed to be a maximizer such that Walras could deduce the necessary calculus conditions for each individual to be maximizing. For each individual, these conditions are in the form of equations, one for each and every good or service. Obviously this involves a huge number of equations in a real economy but this is a mathematics problem so the number does not matter. Together these conditions amount to a system of simultaneous equations and the task is to find a means of specifying the objective functions to assure the logical existence of the unique set of prices that would allow all individuals to be maximizing. Walras thought that the existence of such a set of equilibrium prices was assured whenever the number of equations equaled the number of unknowns (the prices and the quantities of all goods and services transacted). He was in error about this and for many decades mathematical economists would try to create more mathematically sophisticated models that would assuredly entail equilibrium prices and quantities. The first success was not obtained until the 1930s.

It was also realized that proving the existence of a set of equilibrium prices is not enough. Model builders always face two methodological problems. First, if the equilibrium model is to explain why prices are what they are, it must also explain why they are not what they are not. If the model entailed more than one set of possible equilibrium prices, one of those sets may fit the observable prices but since the other sets are also entailed, the question is begged as to why the observed set existed and not one of the other sets. In other words, a model with multiple equilibria is an incomplete explanation of observable prices. Second, even if the model entails a unique set of equilibrium prices, not only must that set be unique but it must be stable. That is, if for any reason the equilibrium is upset (i.e., one or more of the prices deviate from the equilibrium values) will the system return to a state of equilibrium? Any possibility of multiple equilibria aggravates this problem, too. Much of the mathematical work of the 1950s and 1960s was devoted to solving both the existence problem and the stability problem. From a mathematical point of view, many models were provided that were indeed logically sufficient to solve these two problems. But critics would be quick to point out that too often the assumptions made to construct these models were unrealistic.

EQUILIBRIUM MODELS AS A MODE OF EXPLANATION

Leaving aside the mathematical economist who is more interested in the mathematics of equilibrium models than the economy those models are designed to explain, the problems of stability and existence must be dealt with if those models are ever to be a satisfactory explanation or even a useful guide for economic policy. This is particularly so if the equilibrium model is to be used to explain prices. While claiming that the observed price of a good or service is what it is because it is an equilibrium price—that is, it is at a value that allows its market to clear (i.e., allows demand to equal supply)—the explanation is not complete unless one can also explain the how or why the price was adjusted to that equilibrium value.

Any adjustment or change in the price is a decision made by an individual who is not maximizing at the current price. So, if one assumes all demand curves are negatively sloped and supply curves are positively sloped, then for someone to be motivated to change the price it must not be at the value necessary for market equilibrium. In particular, either the price is above the value necessary for equilibrium and thus some supplier is unable to sell the amount necessary for profit maximization or it is below that equilibrium value and at least one demander is unable to buy enough to maximize utility. Kenneth Arrow raised this issue in a 1959 article "Towards a Theory of
Price Adjustment,” where he recognized that textbook theory presumes that all decision makers are in effect small fish in a big pond. That is, all textbook decision makers are price takers because they are too small to have an effect on the going price. But, if the market is in disequilibrium and everyone is a price taker, who changes the price and why? Since textbook economics has maximization as the only behavioral assumption, Arrow said that how much someone changes the price is a decision that must be explained as a maximizing choice. Interestingly, textbooks have an explanation for someone who chooses the price but it is in the chapter about the monopoly producer. While this might be seen as a means of completing the explanation of the price, it creates a contradictory situation. One would have one theory for when the market clears (everyone is a price-taking maximizer) and a different theory for the disequilibrium price adjustment. As every equilibrium model must deal with the dynamics needed to assure stability, it means that both theories must be true at the same time but they are contradictory. This is a very unsatisfactory situation for anyone wishing to use an equilibrium model to explain the one going price, one that clears the market so all participants can be maximizing.

EQUILIBRIUM ATTAINMENT VERSUS THE EQUILIBRIUM PROCESS

Critics of equilibrium model building complain that devoting so much effort to mathematically proving the existence of a possible equilibrium misses the policy point of market equilibrium theory. The primary virtue of a market system as the basis of social organization is not the mathematical properties of a state of equilibrium but the fact that a stable market will always give the correct information to would-be market participants whenever the equilibrium has not yet been reached. A rising price indicates to producers to supply more and to consumers to demand less. But critics also claim the time required to make adjustments to achieve an equilibrium may exceed the time allowed before consumer tastes or technology changes.

In order to recognize an equilibrium process, a model must include an explanation of how the equilibrium is achieved and how long it would take to reach it. Without such recognition, the notion of a market being in a state of equilibrium adds nothing beyond the behavioral assumption of universal maximization. This is so because the assumption of utility maximization is used to explain the individual consumer’s demand decision at any given price and the assumption of profit maximization for the individual producer’s supply decision at that price. Thus if everyone is maximizing at the going price, that price must be the one that clears the market (i.e., the one where demand equals supply)—no other price is logically possible.

EQUILIBRIUM IN PSYCHOLOGY

The concept of equilibrium plays an important role in diverse domains of psychology. At a basic physiological level, an organism strives to regulate drives and to maintain homeostasis—that is, physiological equilibrium. On an emotional level, people work to balance the dictates of competing desires and instincts. At a more cognitive and social level, people strive to reconcile discrepancies among different types of thought, behavior, and attitude. The existence of competing drives, conflicts, and inconsistencies leads to the need to restore equilibrium when a system is out of balance.

Because of the diversity of meanings of equilibrium, psychologists use the term in ways and in contexts that may vary substantially. For instance, the regulatory drives associated with hunger and thirst bear little resemblance to the experience of holding two mutually inconsistent attitudes that must be reconciled. The glue that binds them is the need to maintain a balance. It is this basic need that gives the construct of equilibrium its central role in explaining human and nonhuman behavior at multiple levels.
Beginning with Sigmund Freud's psychodynamic theory, and continuing with that theory's intellectual descendants, equilibrium has played a central role in descriptions of the emotional landscape. At a basic level, Freud postulated that the three components that underlie personality—the id, ego, and superego—exist in dynamic tension, requiring a constant attempt to achieve or retain equilibrium.

The id reflects an unconscious set of instinctive drives solely oriented toward self-gratification. When a need is unmet, the individual is driven to reduce the tension it causes. According to Freud, the id has no contact with reality; its primary process is to form merely an image of the object that will satisfy its drive. At some point, the person needs a reality-based reduction of the drive, not simply an image. The ego was seen to develop from the id to provide an actual reality-based drive-reduction, the so-called secondary process. Freud theorized that this id-ego combination dominates a person's behavior until social awareness leads to emergence of the superego, which recognizes that some behaviors are inappropriate. At that point, the superego needs to be factored into the equation for equilibrium.

The individual must develop equilibrium by maintaining a balance between the need to reduce drives and the need to recognize the realities of behavior within a societal or familial context. When people achieve equilibrium, the forces of the id, ego, and superego are in balance. With disequilibrium, anxiety arises. With realistic anxiety, the rationality of the ego can help resolve the anxiety. With neurotic or moral anxiety, however, the tension caused by the imbalance can lead to the emergence of defense mechanisms that help relieve the anxiety. Freud also speculated that dreaming can help a person resolve anxieties caused by tension between id, ego, and superego.

Subsequent psychodynamic theorists (e.g., Loewinger 1976) have responded to some of the limitations of Freud's theory by shifting the emphasis from id to ego. The goal, however, remains largely the same: to characterize the way people balance basic desires and realities as they adjust to the world around them. Another shift in psychodynamic theories moved from largely internal sources of potential disequilibrium to social sources (Adler 1964; Erikson 1974).

A further psychodynamic theory that features some overlap with Freudian ideas is Carl Jung's analytical psychology. It specifies that one of two attitudes, introversion or extraversion, dominates a person. Two additional sets of dichotomies are important as well: thinking versus feeling—both rational processes—and sensing versus intuiting, which are not rational. People are predisposed, according to the theory, toward one element of each dichotomous pair. The commonly used, but controversial, Myers-Briggs Type Inventory is based on Jung's theory.

The details of these psychodynamic theories differ, sometimes greatly, but each theory, at its base, postulates that people must resolve a series of conflicts as they progress through life. Most of the theories posit that normal sexual or social development requires that people successfully navigate through stages of development, bringing their underlying instincts and motivations into equilibrium.

The humanistic psychologists took a very different approach to understanding people, their motivations, and their behaviors. Whereas the psychodynamic theories rely greatly on unconscious drives and instincts and have a negative cast (i.e., people are always working to resolve crises in order to restore equilibrium), the humanists suggest that people are aware of their motives and are predisposed to full functioning or self-actualization, and that problems arise only when the normal state of equilibrium is breached.

Carl Rogers (1961) speculated that if people are accepted unconditionally, they will develop positive self-regard. On the other hand, if acceptance by oneself or by others is dependent on particular behaviors, people will have difficulty accepting themselves unconditionally. Consequently, their path to self-actualization will be interrupted. According to this framework, disequilibrium occurs when there is a mismatch between people's views of their real self and their ideal self. Such a mismatch prevents self-actualization.

Therapies to remedy such disequilibrium focus on one's own insight into the problem. Rogers's client-centered therapy relies on the therapist's acceptance of and empathy with the clients, who are responsible for resolving their problems. Another humanistic approach, Gestalt therapy, also relies on insight, but the therapist is more directive and may confront the client in order to resolve important issues, so the client can regain equilibrium.

The developmental theory of Jean Piaget relies on the concept of equilibrium in that it maintains that as children become more cognitively sophisticated, they recognize the inconsistency between what they already know and new information they encounter.

Piaget developed the notion of equilibration, which relates to a person's attempt to balance psychological schemas with the new information that he or she
processes. During the process of equilibration, children assimilate new information and new ways of thinking, and then accommodate that new information by changing their psychological schema.

An alternate developmental viewpoint conceived by Lev Vygotsky (1978) postulates that the source of disequilibrium is external. In this view, the disequilibrium that moves children from one stage of development to another is based on social interaction. Vygotsky suggested that differences across cultures affect what children learn and how they learn it. That is, a teacher or parent can elevate children's cognitive complexity beyond the level the children have attained on their own by appropriate help during a learning session. In contrast, Piagetian theories of how children move to new levels of cognitive sophistication are focused on internal processes.

Outside the realm of developmental psychology, social and cognitive psychologists have described the role of equilibrium in social interaction. For instance, Fritz Heider speculated that people embrace new information that is consistent with what they already know and reject incompatible information because of the need to retain balanced cognitive schemas. For example, research has shown that when people engage in a behavior that is inconsistent with a stated attitude, they experience what is known as cognitive dissonance and will often change the attitude to be consistent with the behavior. There are, however, circumstances in which people are able to maintain inconsistent attitudes and behaviors.

EQUILIBRIUM IN PHYSIOLOGICAL THEORY
The body regulates itself in many dimensions simultaneously, each achieving its own balance. Such regulation involves drives such as hunger, thirst, sex, sleep, and others. An early behavioral psychologist, Clark Hull, developed a drive theory that used regulatory mechanisms to predict and explain the emergence of behavior.

According to Hull, an organism rests when in a state of equilibrium. When a drive, like hunger or thirst, develops, the organism is motivated to alleviate this disequilibrium by engaging in appropriate behavior regarding that drive. The act of eating to reduce hunger or drinking to reduce thirst is known as drive-satisfying behavior. Hull developed a complex mathematical theory to characterize the emergence of behavior. The theoretical shortcomings of his concepts led to modifications of the model, however. Contemporary psychologists now employ theories based on the concept of optimum-level. In this framework, the body is viewed as having an optimal level of arousal that differs from one person or animal to another and that differs in varied settings. When arousal is either too high or too low for comfort, the organism engages in behaviors to return the arousal level to the optimal level.

EQUILIBRIUM IN SENSATION AND PERCEPTION
Animals are quite proficient at maintaining appropriate posture, or equilibrium, due to structures in the inner ear that very rapidly provide information to the eyes and to the muscles that regulate balance. The structures responsible for appropriate posture include the three semicircular canals in the inner ear that provide feedback regarding rotational movement of the head and two otolith organs that register linear movement. The canals contain fluids that move when the head moves, creating neural signals about the movement. The otoliths contain calcium carbonate crystals that stimulate neurons when an organism moves.

These five structures send information to the muscles, allowing maintenance of balance even during complex movement. When the structures send information to the eyes, accurate visual tracking of the environment during even rapid head movements is made possible.

EQUITY MARKETS
Firms that want to raise capital have a choice between attracting debt or equity. The main difference between
These financing forms is that debt holders have a contract that states that their claims must be paid in full before the firm can make payments to equity holders. Equity holders are entitled to the rest of the company after the debt holders are paid off. Therefore equity is often referred to as a residual claim. Equity markets, also known as stock markets, are markets where different types of equity are traded. The most common forms of equity are common stocks and preferred stocks. The term common stock is reserved for stock that does not have a special preference in either dividend payments or in bankruptcy. Preferred stock has preference over common stock in dividends and/or bankruptcy.

Equity markets are generally divided into primary and secondary markets. The primary market is where the securities are first offered to the general public. This takes place in the form of a so-called Initial Public Offering (IPO). There is abundant evidence that IPOs are under-priced. This means that the offer price of the shares is, on average, lower than the market price at the end of the first trading day. In 2003 Jay Ritter overviewed evidence on underpricing for thirty-eight countries and found that the average first day returns vary between 5.4 percent for Denmark and 256.9 percent for China. The average first day returns for the United States were 18.4 percent. After the initial public offering, shares can be traded in public secondary markets. These markets can either be organized as an exchange or as an over-the-counter market. An exchange is a physical location where buyers and sellers come together to buy and sell securities. In an over-the-counter (OTC) market buyers and sellers can transact without meeting at a physical place.

The first trading in shares started in 1602 with the formation of the Dutch East Indies Company in Amsterdam. According to Geoffrey Poitras’s Security Analysis and Investment Strategy (2005), the trading of stocks in the United States goes back to 1792 when twenty-one individual brokers and three firms signed the so-called Buttonwood Agreement. In the end this arrangement evolved into the New York Stock Exchange (NYSE), a title that was introduced in 1863. Over time equity markets have expanded enormously. In 1974 the market capitalization of the combined world equity markets was less than $1 trillion. According to Focus, the monthly overview of the World Federation of Exchanges, this total grew to $43.9 trillion at the end of June 2006. At that time, the largest stock exchange in the world, the earlier mentioned NYSE, had a market capitalization of $13.9 trillion and counted 2,205 listed companies. The second-largest exchange, the Tokyo Stock Exchange, had a market capitalization of $4.5 trillion that was accounted for by 2,377 companies. The third-largest exchange in terms of market capitalization is the National Association of Securities Dealers Automated Quotation system (NASDAQ) with a market capitalization of $3.5 trillion. This is an automated quotation system that operates in the United States. Even though its market capitalization is much smaller than that of the NYSE, it has a larger number of listed companies (3,161) than the NYSE. This also illustrates the move from traditional exchanges to automated quotation systems.

Another source of equity is private equity. This is equity that is not traded in public markets. Categories of private equity include venture capital and equity for companies that are in a restructuring process. Private equity funds offer opportunities to invest large sums of money into this type of equity.

In the context of the internationalization of equity markets, firms are often cross-listed on different stock exchanges. Since the United States is the world largest capital market, a large number of firms want to list their equities there. However, this also means that the firms have to submit themselves to the very strict U.S. financial disclosure requirements. In order to avoid these requirements many firms use American Depositary Receipts (ADRs). With an ADR the firm deposits a number of its own shares with a bank in the United States. The bank then issues an ADR; this is a security with a claim on the dividends and other cash flows of the shares that are deposited with the bank. Another internationalization trend that deserves mentioning is the fact that stock markets in emerging economies have become more important. There is a large growth in equity markets in Asia (e.g., Korea and Hong Kong) as well as in Eastern Europe (e.g., Poland and Slovenia). In a number of emerging markets stocks are divided into A and B shares. In such cases the B shares have no or less voting rights than the A shares. foreigners are then restricted to holding the B shares in order to prevent them from taking control over the firm.

ERIKSON, ERIK
1902–1994

Erik Homburger Erikson was born on June 15, 1902, in Frankfurt, Germany. He died on May 12, 1994, in Massachusetts. As a young man, he restlessly traveled through Europe, attending art schools and subsequently teaching art and history in Vienna. Beginning in the late 1920s, while teaching children, he was trained by Anna Freud (1895–1982) as a child psychoanalyst at the Vienna Psychoanalytic Institute. There he met his future wife Joan Serson. In 1933 they immigrated to the United States, where he was offered a teaching position at Harvard Medical School. While teaching, Erikson maintained a private practice in child psychoanalysis. He later held teaching positions at the University of California at Berkeley, Yale University, the San Francisco Psychoanalytic Institute, the Austen Riggs Center in Stockbridge, Massachusetts, and the Center for Advanced Studies of the Behavioral Sciences in Stanford, California, finally returning to Harvard, where he completed his career (Coles 1970).

Erikson invigorated and expanded psychoanalytic theory with concepts he drew from Freud, biology, observations of children from several cultures, and self-observations that emerged from his psychoanalysis. As a clinician and theorist, his central contributions to human development research were to understand and illuminate, not to collect data, regarding both psychopathology and normal growth and development in varied cultural and historical contexts. Among his most important contributions was his eight-stage lifespan approach to personality development, elaborated in Childhood and Society (1950). Another was his introduction of the concept of identity crisis, described in Identity: Youth and Crisis (1968) and exemplified in Young Man Luther (1958). His focus on adolescence and identity crises may have been shaped in part by his own early life stressors, youthful wanderings, and lack of direction (Friedman 1999). His Danish appearance (tall, blond, blue-eyed), inherited from his unknown biological father, contrasted sharply with that of his Jewish mother and his stepfather. His Jewish peers often taunted him at school. He terminated his formal education at the age of eighteen and began his lifetime of travel and questioning. One of his best-known books that exemplifies the individual struggle with justice and reconciliation in a social and historical context is Gandhi’s Truth (1969), for which Erikson won a Pulitzer Prize in 1970.

The underpinning for Erikson’s theory of eight stages of psychosocial (ego) personality development is the biological epigenetic principle. With the proper sequence and rate of development, each stage reaches its time of greatest salience as a healthy individual becomes ready to benefit from experiences provided by significant others relevant to the particular stage crisis. The ego, the central focus of Erikson’s theory, regulates and resolves the tensions between the individual’s psyche and society’s expectations with the goal of a predominance of the syntonic end of the continuum, such as more trust than mistrust. Each stage builds on the preceding stages and prepares one for subsequent stages. The society is initially defined as the mother figure and expands at each stage until it encompasses humankind. Providing an optimistic view of human growth and development, Erikson described the outcome of each stage as modifiable, thus affording the opportunity for growth but also weakness, based on later life experiences. The positive resolution of each stage resulted in a virtue—for trust, for example, the corresponding virtue would be hope. The eight psychosocial stages with their virtues are:

Stage 1: Trust versus mistrust (first year) virtue: hope.
Stage 2: Autonomy versus doubt/shame (one to two years) virtue: will.
Stage 3: Initiative versus guilt (two to four years) virtue: purpose.
Stage 4: Industry/mastery versus inferiority (five years to puberty) virtue: confidence.
Stage 5: Identity versus role confusion/identity diffusion (adolescence) virtue: fidelity.
Stage 6: Intimacy versus isolation (early adulthood) virtue: love.
Stage 7: Generativity versus self-absorption (young and middle adulthood) virtue: care.
Stage 8: Integrity versus despair (later adulthood) virtue: wisdom.

After her husband’s death, Joan Serson Erikson proposed a ninth stage, old age, focused on the effort not to lose one’s “indomitable core” (Davidson Films 1995). Because Erikson’s writings were at times complex and evocative, interpretation of his theory for application to research has resulted in vigorous debate. Nevertheless, all of the personality components have been studied. Identity, a major task of adolescence, has been empirically investigated the most extensively (Kroger 2007; Marcia, Waterman, Matteson, et al. 1993). The concepts of identity and identity crisis have had a major impact on the fields of psychology, sociology, literature, and history, being applied to career, ethnicity, race, sexuality, ideologies, diasporas, and so forth.

Erikson’s lifework continues to be described as one of the most important contributions to the understanding of normal personality development across the lifespan. He is identified as a major factor in the framework and expansion of ego psychology. Erikson was among the first great...
Eroticism

Although there is no accepted definition of *eroticism*, it is understood in this entry to describe the focus of an individual's sexual arousal pattern. It differs from *erota* (the story, picture, or other media), which depicts and appeals to someone's eroticism. A different perspective defines eroticism as a component of sexuality involving a focus on pleasure and the heightening of arousal for its own sake (Kleinplatz 1996).

It is said that anything can be and everything has been eroticized. The subject of an eroticism can be specific or general, stable or fluid over time, and necessary, preferred, or irrelevant for a satisfactory sexual response. The intensity and importance of an eroticism can and does change over time. Sometimes those changes are substantive, sometimes minimal. Eroticisms are idiosyncratic; what one person finds extremely erotic is only somewhat arousing to the next, neutral to another, boring to someone else, and disgusting to the last person. Having an eroticism does not imply necessarily an interest in acting it out; fantasy can be sufficient. Sexual interests may affect each other; an interest in feet, for example, can lead to an interest in shoes. Additionally, a shoe eroticism may be expressed differently depending on sexual orientation (e.g., work boots for a homosexual man and high heels for a heterosexual man).

Every society attempts to restrict the sexual behavior of its members, even though they are usually unsuccessful. The control methods include making the act (or even a depiction of the act) a crime, immoral, a violation of religious teachings, or pathognomonic of an illness. Individuals who flout the societal mores are subject to imprisonment, shunning, eternal damnation, medical or surgical interventions, involuntary hospitalization, and civil penalties. Individuals have been imprisoned or disowned and have lost jobs, inheritances, security clearances, custody of their children, their standing in the community, and their marriages for violating these mores. This can involve admitting an interest in, promoting acceptance of, distributing or creating depictions of, or engaging in the proscribed acts.

Societal attempts to control an eroticism often include trying to censor the erotica, now labeled as indecent or obscene, that depict that eroticism. What legally constitutes obscenity continues to be debated extensively; it varies from society to society, within each society, and changes over time. What was once accepted can become proscribed and what was proscribed can become accepted.

A basic and unanswered question is how specific eroticisms develop and how many different developmental mechanisms exist. Other important social science questions include: What is the importance of having eroticisms? Why does every society try to control eroticisms and fail? How can eroticisms be changed or influenced? What is the relationship between sexual orientation and eroticism? How do the eroticisms of men and women differ?

There is great debate among both professionals and the public concerning the effect of exposure to sexually explicit material on one's eroticism or sexual behavior. We know eroticisms can evolve or change over time, but psychotherapy has been ineffective in directing those changes purposefully. Although controversial, it is improbable that exposure to erotica has any significant or lasting effect on one's sexual interests, or they would be easy to change. It is more probable that exposure allows individuals to recognize the nature of their own eroticism. Additionally, there is great concern about the effects of erotica on minors. Some believe that the material will provoke the minor to engage in the depicted sexual activity or incorporate it into a new eroticism; others suggest that lack of exposure stymies sex rehearsal play, which eventuates in adult sexual dysfunction or other sexual concerns.

Although rare, there are people who have no eroticism. These individuals often present with inhibited sexual desire, arousal difficulties, indifference or, avoidance of sex. Nevertheless, on further evaluation they are quite capable of a “normal” sexual response; they just have nothing upon which to focus sexually.
Recognition of one’s eroticisms enhances an individual’s sex life, can enrich a couple’s sex interactions, helps individuals connect with others who share their eroticisms, and promotes a feeling of completeness as a person.

ERROR-CORRECTION MECHANISMS
Consider an econometric model of a dynamic relationship between a variable \( y_t \) and explanatory variables \( x_{1,t}, \ldots, x_{p,t} \), taking the form

\[
y_t = \beta_0 + \beta_{11} x_{1,t} + \cdots + \beta_{1k} x_{k,t} + \beta_{21} x_{1,t-1} + \cdots + \beta_{2k} x_{k,t-1} + \beta_3 y_{t-1} + u_t
\]

where \( u_t \) is a random error term. An alternative representation of this model is

\[
\Delta y_t = \gamma_0 + \Delta \gamma_1 \Delta x_{1,t} + \cdots + \gamma_{1k} \Delta x_{k,t} + \gamma_2 (y_{t-1} - \delta_1 x_{1,t-1} - \cdots - \delta_k x_{k,t-1}) + u_t
\]

where \( \Delta y_t = y_t - y_{t-1} \) and \( \Delta x_{i,t} = x_{i,t} - x_{i,t-1} \) for \( i = 1, \ldots, k \), and the relationships between the coefficients are \( \gamma_0 = \beta_0, \gamma_{1i} = \beta_{1i}, \gamma_{2i} = \beta_3 - 1, \) and \( \delta_i = (\beta_1 + \beta_2)/(1 - \beta_3) \).

Equation (1) is sometimes called the autoregressive distributed lag (ARDL) representation, while (2) is the error correction mechanism (ECM) representation. Generalizations to higher orders of lag are easily obtained. The ECM representation has the attractive features of representing an economic agent’s decision in terms of a rule-of-thumb response to current changes, according to parameters \( \gamma_{1i} \), and corrections to deviations from a desired long-run equilibrium relation with parameters \( \delta_i \). For this reason the acronym ECM is sometimes taken to stand for equilibrium correction mechanism. Equation has the disadvantage of being nonlinear in parameters, so that estimation and inference are less straightforward than in the case of equation.

The ECM form was first proposed by Denis Sargan (1924–1996) for a model of wages and prices (Sargan 1964). It was subsequently popularized by the work of David Hendry and others in the context of modeling applications in macroeconomics, such as the consumption function and the demand for money. The seminal contribution is J. E. H. Davidson, D. F. Hendry, F. Srba, and J. S. Yeo (1978), commonly referred to in the literature as DHSY.

The approach later acquired special prominence due to the work of Clive W. J. Granger, who independently explored the implications of modeling economic time series as integrated (I(1)) processes; in other words, processes generated as the partial sums of stationary, weakly dependent increments. (A random walk is a simple example.) This type of model, also called a stochastic trend model, describes many series observed in economics and finance. If in the driving processes \( x_{1,t}, \ldots, x_{k,t} \) are I(1), and \( \gamma_2 < 0 \), then \( y_t \sim I(1) \) also, but

\[
z_t = y_t - \delta_1 x_{1,t} - \cdots - \delta_k x_{k,t}
\]

is I(0) (i.e., a stationary, weakly dependent process). The variables are then said to be cointegrated and \( z_t \) is called the cointegrating residual. Cointegration (i.e., combining the twin modeling concepts of stochastic trend representations for economic series and cointegrated relations characterizing long-run interactions over the economic cycle) has been a profoundly influential idea in macroeconomics, earning Robert F. Engle and Granger (1987) the Nobel Prize for economics in 2003.

In practice, such models are often generalized to a system of dynamic equations, explaining several variables in terms of a common set of cointegrating relations. In reduced form the resulting models are called vector error correction models (VECMs) or reduced rank vector autoregressions (VARs). Following the work of Søren Johansen, a closed VECM for an \( m \)-vector of variables \( x_t \) is commonly represented in matrix notation as

\[
\Delta x_t = \Gamma_0 + \Gamma_1 \Delta x_{t-1} + \cdots + \Gamma_k \Delta x_{t-k} + \alpha \beta' x_{t-1} + u_t \quad (m \times 1)
\]

where \( z_t = \beta' x_t (s \times 1) \) is the vector of cointegrating residuals. The rank of the \( m \times s \) matrices \( \beta \) and \( \alpha \) is called the cointegrating rank of the system. In a cointegrated system the inequalities \( 0 < s < m \) must hold. The Granger representation theorem states that a linear dynamic model generates cointegrating relations if and only if it has a VECM representation.

Errors, Standard

Reports of the values of sample statistics (e.g., means, or regression coefficients) are often accompanied by reports of the “estimated standard error.” A statistic is simply an index or description of some characteristic of the distribution of scores on a variable in a sample. The “standard error” associated with the statistic is an index of how much one might expect the value of the statistic to vary from one sample to another. The estimated standard error of a sample statistic is used to provide information about the reliability or likely accuracy of the sample statistic as an estimate of the population parameter.

For example, the 1,514 adults responding to the *General Social Survey* (National Opinion Research Center 2006) for 1991 reported that their average age was 45.63 years. Along with this statistic, a “standard error” of .458 was reported. This suggests that if we were to draw another sample (of the same size, using the same methods) and to calculate the mean age again, we might expect the result to differ by about .458 years from that in our first sample.

Definition

Formally, the standard error of a statistic is the standard deviation of the sampling distribution of that statistic. Most texts in estimation theory in statistics contain detailed elaborations (e.g., Kmenta 1986, chapter 6). Some elaboration in less formal terms, however, may be helpful.

When we select a probability sample of cases from a population, collect data, and calculate the value of some statistic (e.g., the mean score on the variable age), we are using the sample statistic to estimate the mean of the whole population (the population parameter). If we were to draw additional samples and calculate the mean each time, we would expect the values of these sample means to vary because different cases will be included in each sample. The random variation of the value of a statistic from one sample to another is termed the sampling variability of the statistic.

Imagine that we collected the values of a statistic from a very large number of independent samples from the same population, and arrayed these values in a distribution. This distribution of the values of a statistic from repeated samples is termed the sampling distribution of that statistic. The statistic (e.g., average age) will sometimes be somewhat lower than the average of all samples, and sometimes higher. We can summarize how much any one sample is likely to differ from the average of all samples by calculating the standard deviation of sampling distribution. This value is the standard error; it is the average amount by which the value of the statistic in any one sample differs from the average value of the statistic across all possible samples.

Uses of the Standard Error

The estimated standard error of a statistic has two primary uses. First, the standard error is used to construct confidence intervals; second, the standard error is used to conduct hypothesis tests for “statistical significance.”

In the example above, the mean age of persons in the sample was 45.63 years. The estimated standard error of this statistic was .458 years. Most observers would conclude that our estimate of the population age is fairly accurate—that is, if we drew another sample, it would be expected to differ very little from the current one. On
average, the differences between samples will be less than one-half year of age (.458 years).

It has been proven that the sampling distribution of sample means has a normal or Gaussian shape. Because this is true, we can describe the reliability of the sample estimate with a confidence interval. In the case of our example, the “95 percent confidence interval” is equal to the value of the sample statistic (45.63) plus or minus 1.96*.458 (the standard error). That is: 95 percent of all possible samples will report a value of the mean age between 44.73 years and 46.52 years. Confidence intervals are a common way of summarizing the reliability of inferences about population parameters on the basis of sample statistics. Large standard errors indicate low reliability (wide confidence intervals); small standard errors indicate high reliability (narrow confidence intervals).

Standard errors are also used in the process of “hypothesis testing” to determine “statistical significance.” In hypothesis testing, we propose a “null” hypothesis about the true value of a population parameter (e.g., a mean). We then calculate a “test statistic” that is used to determine how likely the sample result actually observed is, if the null hypothesis is true. Test statistics usually take the general form of: ((value observed in sample – value proposed by the null hypothesis) / standard error). Our decision about whether a sample result is likely, assuming that the null hypothesis is true, is based on the size of the observed difference of the sample from the hypothesis relative to sampling variability—summarized by the standard error.

ESTIMATING STANDARD ERRORS
Most reports will show the “standard error” as “estimated” (even if they do not use this terminology, the values reported for the standard errors are probably estimates). When we conduct a study, we usually collect information from only one sample. To directly calculate the sampling distribution and standard error, we would need to collect all possible samples. Hence, we rarely know the actual value of the standard error—it is itself an estimate.

Statistical theory and research has provided a number of standard formulae for estimates of standard errors for many commonly used statistics (e.g., means, proportions, many measures of association). These formulae use the information from a single sample to estimate the standard error. For example, the common estimator of the standard error of a sample mean is the sample standard deviation divided by the square root of the sample size. When computer programs calculate and print standard errors, calculate confidence intervals, and perform hypothesis tests, they are usually relying on these standard formulae.

The standard formulae, however, assume that the observed sample is a simple random one. If this is not the case, the estimates may be wrong. If the actual sampling methodology used involves clustering, estimated standard errors by the standard formulae may be too small. Consequently, we may reach incorrect conclusions that our estimates are more reliable than they actually are, or that null hypotheses may be rejected when they should not be. If the sampling methodology actually used involves stratification, estimated standard errors by the standard formulae may be too small. Consequently, we may think our point estimates of population parameters are less reliable than they actually are; we may fail to reject null hypotheses that are, in fact, false.

Where probability sampling designs are not simple random, there are several alternative approaches to estimating standard errors. For some complex survey designs, more complex formulae are available, as, for example, in the statistical packages Stata (Stata Corporation 2006) and Sudaan (Research Triangle Institute 2006). In other cases, “bootstrap” and “jackknife” methods may be used (Efron and Tibshirani 1993).

Bootstrap methods draw large numbers of samples of size N from the current sample, but with replacement. Bootstrap samples are the same size as the original sample, but contain “duplicate” observations. For each of a very large number of samples (1,000 to 10,000), the statistic of interest is calculated. These estimates are then used to construct the sampling distribution, from which the standard error is estimated. Large sample sizes are required for bootstrap methods.

Jackknife estimators divide the current sample into many random samples that are smaller than the full sample, but are drawn without replacement. Large numbers of samples are selected, and the statistic of interest is calculated for each sample. This then allows the calculation of the sampling distribution and the estimated standard error.

ESSENTIALISM
Essentialism is the idea that members of certain categories have an underlying, unchanging property or attribute (essence) that determines identity and causes outward behavior and appearance. An essentialist account of gender, for example, holds that differences between males and females are determined by fixed, inherent features of those individuals. The doctrine of essentialism is widespread in practice, underlying many approaches (both historical and current) in the biological sciences, the social sciences, and cultural studies. Essentialist ideas underlie much lay skepticism toward biological evolution; such ideas saturate discussions of race and gender as well as of ethnicity and nationality. In gender studies, essentialism has been important as a focus of criticism and, less often, as an explanatory strategy (e.g., the notion of a “gay gene”).

TYPES OF ESSENTIALISM
Essentialism may be divided into three types: sortal, causal, and ideal. The sortal essence is the set of defining characteristics that all and only members of a category share. This notion of essence is captured in Aristotle’s distinction between essential and accidental properties. For example, on this view the essence of a mother would be the property of having given birth to a person (rather than an accidental property, such as baking cookies). In effect, this characterization is a restatement of the classical view of concepts: Meaning (or identity) is supplied by a set of necessary and sufficient features that determine whether an entity does or does not belong in a category. However, the viability of this account has been called into question by psychological research on human concepts. The causal essence is the entity or quality that causes other category-typical properties to emerge and be sustained, and that confers identity. The causal essence is used to explain the observable properties of category members. Whereas the sortal essence could apply to any entity, the causal essence applies only to entities for which inherent, hidden properties determine observable qualities. For example, the causal essence of water may be something like H₂O, which is responsible for various observable properties that water has. Thus, the cluster of properties “odorless, tasteless, and colorless” is not a causal essence of water, despite being true of all members of the category, because the properties have no direct causal force on other properties.

The ideal essence has no actual instantiation in the world. For example, on this view the essence of “justice” is some abstract quality that is imperfectly realized in real-world instances of people performing just deeds. None of these just deeds perfectly embodies “justice,” but each reflects some aspect of it. Plato’s cave allegory (in The Republic), in which what we see of the world are mere shadows of what is real and true, exemplifies this view. The ideal essence thus contrasts with both the sortal and the causal essences. There are relatively little empirical data available on ideal essences in human reasoning.

CRITICISMS OF ESSENTIALISM
Essentialism is often implicit. Theorists rarely self-identify as essentialist; more often, a position is characterized as “essentialist” by others, typically as a form of criticism. Essentialist indications include a cluster of separable ideas—for example, treating properties as genetically rather than socially determined, assuming that properties are immutable, or assuming that a category captures a wealth of nonobvious properties, thereby having the potential to generate many novel inferences (e.g., Arthur R. Jensen’s arguments in his 1969 article regarding racial differences in IQ). Any of these assumptions could be considered evidence for an essentialist framework.

In the social sciences, essentialist accounts are highly controversial. Essentialist accounts of race, ethnicity, or gender have been criticized for reducing complex, historically contingent effects to fixed and inherent properties of individuals. Anti-essentialist accounts emphasize the importance of social context, environmental factors, and structural factors (including economics and class). Such accounts are often grouped together under the heading social (or cultural or discursive) constructionism; as Laura Lee Downs noted in her 1993 article, at their best they provide detailed accounts of the social reproduction of gender, ethnic, and racial categories, and at their worst slide into voluntarism. An important analytic strategy, put forward by Fredrik Barth in 1969 and Judith Irvine and Susan Gal in 2000, has been to eschew an account of the categories of social groups in favor of examining the social and cultural conditions by which they are differentiated.

Racial categories illustrate the perils and shortcomings of essentialism. Although race is often essentialized, anthropologists and biologists widely agree that race has no essence. The superficial physical dimensions along which people vary (such as skin color or hair texture) do
not map neatly onto racial groupings. Observable human differences also do not form correlated feature clusters. Skin color is not predictive of “deep” causal features (such as gene frequencies for anything other than skin color). There is no gene for race as it is commonly understood.

Culture frequently serves as a stand-in for race in social essentialist frameworks, as it did in South Africa under the apartheid regime. The doctrine of ethnic primordialism (that ethnicities are ancient and natural) was a popular explanatory device in the 1950s and 1960s to account for apparent ethnic and regional fissures in the developing world. It returned after the fall of the Berlin wall to account for the instability of former socialist republics, most dramatically in Yugoslavia, and remains a powerful force in international relations despite the availability of nuanced, nonessentialist explanatory accounts.

Essentialism is also criticized for its political and social costs, in particular for encouraging and justifying stereotyping of social categories (including race, gender, and sexual orientation), and perpetuating the assumption that artificial distinctions (such as caste or class) are natural, inevitable, and fixed. Nonetheless, some feminists and minorities appropriate essentialism for their own group(s)—at least temporarily—for political purposes. Strategic essentialism, Gayatri Spivak’s term from her 1985 study, can devolve into an embrace of essentialism, with the argument that essential differences are deserving of celebration. Other theorists, while recognizing many of the problems of essentialism characterized above, have proposed that at least some tenets of essentialism (e.g., that categories may have an underlying basis) are rooted in real-world structure.

However, criticisms of essentialism extend to biological species as well. In the case of biological species, essentialism implies that each species is fixed and immutable, thus leading Ernst Mayr to note, “It took more than two thousand years for biology, under the influence of Darwin, to escape the paralyzing grip of essentialism” (1982, p. 87). An additional concern, for biological as well as social categories, is that essentialism assumes that the essence is a property of each individual organism. In contrast, according to evolutionary theory, species cannot be characterized in terms of properties of individual members but rather in terms of properties of the population. Elliott Sober (1994) distinguishes between “constituent definitions” (in which groups are defined in terms of characteristics of the individual organisms that make up the group) and “population thinking” (in which groups need to be understood in terms of characteristics of the larger group; e.g., interbreeding populations, in the case of species). Sober suggests there is no essence for biological species—let alone groupings of people, such as races—at a surface level or even at a genetic level.

PSYCHOLOGICAL ESSENTIALISM

Some psychologists, such as Susan A. Gelman in her 2003 book and Douglas Medin in his 1989 article, have proposed that (causal) essentialism is a cognitive bias (psychological essentialism) found cross-culturally and even in early childhood, with important implications for a range of human behaviors and judgments: category-based inductive inferences, judgments of constancy over time, and stereotyping. Psychological essentialism requires no specialized knowledge, as people may possess what Medin calls an “essence placeholder” for a category, without knowing what the essence is. Preschool children expect category members to share nonobvious similarities, even in the face of obvious dissimilarities. For example, on learning that an atypical exemplar is a member of a category (e.g., that a penguin is a bird), children and adults draw inferences from typical instances that they apply to the atypical member (e.g., they infer that penguins build nests, like other birds). Young children judge nonvisible internal parts to be especially crucial to the identity and functioning of an item. Children also treat category membership as stable and unchanging over transformations such as costumes, growth, metamorphosis, or changing environmental conditions. Therefore, essentialism as a theoretical construct may emerge from fundamental psychological predispositions.

ETHICS

Ethics in the social sciences can be best understood by distinguishing normative ethics from metaethics. Normative ethics derives from the practical purpose of guiding how we ought to live and inquires into the proper guidelines of conduct for a responsible human being. Metaethics asks what ethics is, how it can be distinguished from other forms of human practice, and where it finds its proper place. Twentieth-century social science was dominated by normative ethical questions: questions about what ethical guidelines a professional social scientist should adopt. Normative ethics dominated the discussion because social scientists generally took the model of professional ethics—institutionalized in the codes of conduct and peer review committees of associations of (among others) legal or medical practitioners—for granted. This preoccupation with professionalist models reduced social scientists' interest in metaethics and thus their capacity to understand what ethics is. Since the 1970s, however, processes of "deprofessionalization" or "horizontalization" have reduced the independence of professional practitioners, giving rise to new forms of institutionalizing ethics and increasing the demand and opportunity for metaethical reflection.

In the context of the rise of the welfare state's demand for expertise, sociologists, in particular, propounded a folk ideology of professionalism, and its model of ethics—of safeguarding the quality of professional service by codes of conduct administered, in the case of conflict, by a committee of peers—was adopted by social scientists from the 1950s onward. Two famous cases in social psychology—one in which religious informants seemed misinformed about researchers' own beliefs (Smith 1957), and another where experimental subjects appeared to be put under intolerable stress (Milgram 1964)—became paradigmatic in sensitizing many social scientists to the possible abuse of people researched. In addition, anthropologists and sociologists were worried by the use of research for U.S. counterinsurgency operations in Latin America and Southeast Asia, and made the interests of people researched paramount in their first ethical codes. This resulted in guidelines of conduct that focused predominantly on the responsibility to avoid doing unnecessary harm to research subjects—by the experimental situation itself, by secret or clandestine research, or by insufficiently protecting the research subjects' privacy. When institutionalized by social scientific associations around 1970, such codes and committees were primarily seen as a prerogative of professionals, whose expertise allowed them to speak for or interpret the interests of "clients." This assumption of professional autonomy remains dominant today in many ways. Most social scientists think that an ethical code is a necessary and self-evident element of their profession, despite the fact that they managed without codes for half a century or more.

In society at large, however, professional autonomy decreased by changing practices of professional control. In the field of ethics, this was particularly manifested by the increasing insistence on the right to "informed consent" of people researched, adopted from the medical profession since the mid-1960s. If "informed consent" already "horizontalized" the professional expert's relationship to some of his audiences, the increasing employment of social scientists outside the university system since the late 1970s forced them to be more explicitly responsible to private employers and sponsors as well. While some protested this dual loss of professional autonomy, others embraced the new ethics of accountability to sponsors and people researched—although neither group always knew how "accountability" was tied to the spread of neoliberal market models and auditing techniques throughout the academic world.

These developments implied new institutionalizations of ethical practice: From the 1980s onward, codes of conduct and "good practice" mushroomed, but now increasingly produced by universities or funding agencies rather than professional associations. These institutions' internal review boards introduced ethical audits, for example, at the level of the grant application, thus increasing the possibility of external control of practitioners by ethical codification (while previously, codes were aimed at safeguarding the practitioners' professional autonomy). Meanwhile, professional social science associations reduced their involvement in ethical arbitration (partly because, unlike the medical or legal professions, they could not effectively sanction violations of their codes) and fell back more insistently on the role of the ethical code in professional public relations and education. Surprisingly, such pleas for an education in ethics often focus on teaching by codes rather than by the more appro-
This crisis of the professional model exacerbated existing problems with normative ethics, and especially with ethical codification. In the professional model, the ethical code presupposes a community of scholars who hold each other accountable to its guidelines, but this Enlightenment conception of social contract breaks down once infractions of these guidelines cannot be sanctioned. Moreover, when the membership of such communities is not exclusive, practitioners may find themselves subject to the rules of a multiplicity of organizations (including, of course, ordinary citizens’ duties)—a situation in which most members of social scientific associations find themselves. The adoption of codes of conduct by universities and funding bodies is criticized for merely increasing the means of such institutions’ internal control, while failing short of achieving its actual goal: improving academic practice. This gives rise to the metaethical question of whether one can speak of an administrative fetishization of ethical codes, and whether this distracts from academic ethical awareness, so that ethical codes reduce rather than promote ethical practice (Bauman 1993). The answer to this question is not unequivocal: the codification of good practice may be a necessary instrument to sensitize practitioners to the possibility of doing harm (there is, for example, surprisingly little agreement on the ethics of research into human genetics). Once a code is in place, however, it can perform some of the less desirable functions mentioned above.

Other recent metaethical reflections radically broaden social scientific ethics, if only because they do not restrict themselves to normative ethics and the do’s and don’ts of the research relationship. Inspired by philosophers such as Michel Foucault (1926–1984) or Charles Taylor, social scientists increasingly discuss ethics as the way in which people constitute themselves—and others—as subjects, by not just considering what it is “right to do” but, more broadly, striving after “what it is good to be” (Taylor 1989, p. 3). In this way, ethics is recognized as part of the everyday technologies of the self, and therefore as a topic of social scientific study in its own right, claiming a place next to and in comparison with law, politics, or economics (among other things) in understanding human behavior. Thus, sociologists of culture can be seen to study ethics when discussing, for example, the Protestant or the romantic ethic.

The comparative study of ethics, started by the Finnish anthropologist and philosopher Edward Westermarck (1862–1939) around 1900 and only feebly followed up by anthropologists in the 1950s and 1960s, may be revived. Such studies also open up spaces for alternative models of ethics: sociocultural anthropologists and archaeologists, for example, have explored a model of open-ended ethical negotiation (Meskell and Pels 2005)—an ethics as necessary for the research relationship as it is for human behavior in general. Such explorations can also question the implicit distinction between fact and value that still often keeps the teaching of research methodology apart from the teaching of research ethics, impoverishing social science education in the process. It seems obvious that only the latter move—toward a full integration of ethics and methodology—can lead to a truly ethical social scientific practice, in which students are made aware of the situational, case-bound ethics of research from the moment they start their first training.

**ETHICS, BUSINESS**

When discussing the subject of business ethics, points of view range from those who believe that ethics in business is one of the most pressing issues if companies are to ensure credibility and trust to the cynic who is of the view that the term business ethics is an oxymoron, a contradiction in terms, and that the concepts of ethics and business are inherently incompatible. In the early twenty-first century, the general public, fueled by the general media, is quick to seize upon ethical wrongdoing by both small and large companies and is anxious to spotlight ethical violations. In doing so, demands are also increasing for greater levels of accountability in business. The reality, therefore, is that the term ethics—the expectation of appropriate behavior—and business—the current mercantile environment—cannot be separated as one experiences increasing expectation of higher standards of ethical behavior in organizations.
FACTORS PROMOTING ETHICAL AWARENESS

The factors promoting ethical awareness in both business organizations and business education programs are varied. Societal expectations and tolerance of what constitutes appropriate business conduct have also broadened. For example, companies such as Nike and Reebok have had to fend off criticisms of sweatshop practices in their off-shore contract manufacturing facilities by posting their factory labor audits on the Fair Labor Association (FLA) Web site. Both consumer and shareholder attitudes toward an organization and its ethical profile are increasingly impacting on purchasing decisions and investment strategy. Examples are the consumer boycotts, as historically experienced by Nestlé, and also the growing popularity of ethical investment funds. Undoubtedly, media attention has been instrumental in highlighting ethical misdemeanors. The popular press has been littered with high-profile cases such as Enron, WorldCom, Parmalat, and Adelphi Communications, as well as the audit companies who appear to have been complicit in their oversight of the financial practices of those organizations. The potential cost of ethical violations is also a motivating factor for organizations to reassess their stance. Companies such as Ford, for example, have been subject to significant compensation claims in relation to endangering consumer welfare as a result of faulty tires used on the Ford Explorer.

Ethical violations, when made public, can have a damming effect on publicly listed companies, as supported by the efficient market hypothesis, which maintains that markets are very efficient in interpreting data and arriving at equilibrium prices. Share prices reflect publicly available information, and it appears that any unethical conduct that is discovered and publicized impacts the corporation and shareholders by ultimately lowering the value of a company’s shares for an appreciable period of time. Similarly, for unlisted companies it is assumed that when an ethical violation is made known it will erode the trust of consumers and will ultimately be reflected in diminished sales.

The relationship between ethical behavior and company performance is intriguing. More than ninety-five empirical studies have examined the effect of the relationship between ethics and corporate social responsibility on financial performance, with the outcomes being both positive and negative. Positive relationships prevailed but it is not entirely clear whether increased ethical activity leads to increased performance or, alternatively, whether higher performance provided firms with additional resources that they could devote to social and ethical activities. Furthermore, there are varying levels of ethical engagement by organizations. The first level is one of self-protection; that is, ethical behavior is promoted in order to avoid criminal liability or additional costs. The next level is reputational awareness and the associated benefits that accrue to the organization. The final level is when an organization has an interest in being ethical because it believes it is, in fact, the right thing to do; it is the way the company does business.

MORALITY AND ETHICS

While it is tempting to think of business entities as the primary moral agent, business organizations are, in fact, commonly comprised of a number of individuals making decisions that may have an ethical dimension. These ethical dimensions could relate to environmental and social considerations, such as pollution; stakeholder interactions, for example, product liability; competitive dealings, for example, price collusion; employer obligations, for example, employee safety; or personal behavior, for example, conflict of interest, so it is important to realize that the ethical performance of an organization is a reflection of the individual behavior of its employees. What guides this behavior? Essentially, morality relates to principles of right and wrong and is comprised of numerous moral norms or standards. These moral expectations have a number of sources such as family, society, church, education, training, and even one’s organization or employment. This is the intellectual base one frequently refers to when faced with an ethical dilemma (the head part). Ethics is the discipline of dealing with moral duty and obligation and might be described as the practice of morality (the actual behavior part). Business ethics is, therefore, the practice of morality as it applies to business behavior.

There is extensive scholarly debate on whether moral principles apply universally, or whether ethical judgments are relative to their context. The ethical relativists assert that there is no consistency of beliefs because moral principles are relative to individual persons and cultures, so moral standards will differ between individuals, groups, circumstances, and across time. The absolutists, however, contend that there are common moral standards upon which ethical reasoning rests and that, despite variations in ethical behavior, individuals are rooted in common moral standards. In support of the absolutists, it has been suggested that because the purpose of morality is to help make social cooperation possible, moral principles are universally necessary for that to occur.

As one witnesses the differing ethical behavior being exhibited in companies it has been suggested that there are varying levels of moral development. According to Lawrence Kohlberg’s well-established stages of moral development, there are six stages of moral development that can be summarized into three levels: the preconventional level is one at which individuals are motivated by a
childlike avoidance of punishment, obedience to authority, fear, and self-interest. At the conventional level, individuals are motivated by loyalty to a group or professional norms. At the highest level, postconventional, individuals have a wide view of what is right and wrong and of those who might be affected by their decisions. An individual operating at this level has broad ethical principles in place and his or her decisions are based not on the current norms of the group or standards of society, but on personal conscience grounded in these principles.

THE RESEARCH LITERATURE
Historically the literature on business ethics has been anchored in normative philosophy and can be seen to be broadly delineated into three areas: prescriptive/hortatory literature, which attempts to sermonize and instruct the business community and education in raising ethical standards; descriptive/positive literature, which is characterized by extensive empirical research into, for example, ethical attitudes of students and business personnel; and meta ethical/analytical literature, which investigates meaning and justification relating to the corporate and individual decision-making process. Naturally, the field of business ethics is readily evolving. The colloquy on business ethics is being extended with the lexicon broadening and being claimed by related terminologies such as corporate social responsibility, stakeholder management, corporate governance, sustainability, and corporate citizenship.

ETHICS IN EXPERIMENTATION
Experimentation in the social sciences, by its very nature, requires researchers to manipulate and control key aspects of the social setting so as to determine what effect, if any, these manipulations have on the people in that setting. Such studies, although unmatched in terms of their scientific yield, nonetheless raise questions of ethics: Do researchers have the moral right to conduct experiments on their fellow human beings? What practices are unacceptable and what procedures are allowable? Can standards be established to safeguard the rights of participants?

ETHICAL CONTROVERSIES AND HUMAN RESEARCH
Historically, ethical concern for the rights and well-being of participants in social science research emerged in the context of a heightened public scrutiny of all forms of research with human participants. This scrutiny resulted from the public debate surrounding a series of research projects dating back to the mid-1930s. As early as 1932, physicians in the United States, with sponsorship by the Public Health Service, began a study on the effects of untreated syphilis. This project, commonly known as the Tuskegee syphilis study, continued until 1973, even though penicillin was accepted as an effective cure for this disease in the 1940s. During World War II (1939–1945), German physicians conducted a series of appalling medical experiments in concentration camps, in which prisoners were routinely used to test the effectiveness of various procedures, with fatal results. From 1944 to 1974, U.S. researchers studied the effects of radiation poisoning by injecting people with plutonium without their consent. In the late 1950s, a drug manufacturer paid physicians to administer the drug thalidomide to patients, who were not warned that the drug was an experimental one not yet approved for general use. The drug caused birth defects when taken by pregnant women (Dunn and Chadwick 2002).

These studies raised fundamental questions about the rights of individuals and the ethical responsibilities of investigators. Physicians have long been bound by the oath of “do no harm,” yet all these projects violated this principle of beneficence. Investigators denied participants basic freedoms of choice and self-determination, and they acted unjustly when they selected subjects based on prejudice and antipathy. The horrific German medical studies singled out for study Jews held illegally in Nazi concentration camps, and the Tuskegee syphilis study used disadvantaged, rural black men. These studies exploited people who society is duty-bound to protect.

Although social science research was considered relatively risk-free in comparison to these biomedical studies, Yale psychologist Stanley Milgram’s 1963 study of obedience suggested that behavioral studies could also harm participants in significant ways. Milgram recruited volunteers from the local community to take part in what they
thought was a study of learning. The volunteers were ordered by the experimenter to give increasingly powerful and painful electric shocks to another participant whenever he made mistakes. The other participant was, in reality, a member of the research staff who deliberately made errors during the procedure. He did not actually receive any shocks, but he feigned pain and eventually begged to be released. Milgram, by using this elaborate procedure, discovered that the majority of the people he studied obeyed the experimenter's orders, and many experienced extreme distress during the procedure. He reported that fourteen of the forty original participants were seized by fits of nervous laughter, and three displayed "full-blown, uncontrollable seizures" (Milgram 1963, p. 375).

STANDARDS AND SAFEGUARDS
Public inquiry into these cases of scientific malfeasance resulted in the promulgation of codes of conduct for experimentation with human participants. The tribunal that judged the German doctors developed the Nuremberg Code, which stresses the importance of voluntary consent, the scientific value of the procedure, and the minimization of physical and mental suffering. In 1964 the World Medical Association issued the Declaration of Helsinki to clarify the ethical boundaries between therapeutic and nontherapeutic research. The U.S. Congress, in 1974, mandated the formation of the National Commission for the Protection of Human Subjects, and this commission crafted a set of guidelines commonly called the Belmont Report. This report stresses the need for consent, the protection of vulnerable populations, and the fair treatment of all participants. Professional associations, including the American Medical Association and the American Psychological Association, have also promulgated standards of ethics for investigators, and censure those members who violate their standards.

These standards of conduct for experimental research with human participants all recognize the substantial benefits of scientific research, but require that these benefits be weighed against the risk the research creates for participants. Possible risks include invasion of participants' right to privacy, physically or psychologically harming participants, subjecting participants to public embarrassment or legal sanction, and wasting their time and money. Ethicists also suggest that the use of deception by researchers, although necessary in order to gain valid data about their spontaneous reactions to social stimuli, may engender distrust and contribute to the dehumanization of research participants. Although these risks are offset, in part, by specific benefits for participants (such as monetary payment, educational gains, increased self-understanding, and self-appropriation for having helped further scientific research), the key benefits are the contribution of the work to society and scientific knowledge. When risks to subjects are too great, researchers must use low-risk alternatives, such as nonexperimental procedures or simulations.

Ethical guidelines also require that participants be fully informed about the procedures and their risks, and that their understanding of these risks be documented in some way. In most laboratory experiments, the researcher provides participants with a brief but accurate description of their duties in the research and then gives them a choice to participate or not. This practice is known as informed consent, and it serves to remind subjects that they can terminate their participation in the study at any time if they choose to do so. In cases where the possibility of harm is negligible, then the requirement for consent can be waived, as it also would be when documentation of consent will harm participants by making them identifiable. If individuals are unable to provide full consent, because their autonomy as individuals is limited, then they must be afforded special protections. Children, for example, cannot fully understand or provide consent, and their parents’ consent is required. Similarly, institutionalized individuals, such as prisoners, can only take part in research if they are completely uncoerced and if the risks posed by the study are minimal.

Most researchers also fully clarify the hypotheses once the study is over. This phase of the research process is typically known as debriefing, and it involves reviewing the hypotheses with participants, answering any questions, and removing any harmful effects of the experience. Such a debriefing phase is particularly critical when the investigator did not provide the participants with a full disclosure of the purposes of the study during the consent process—as is often the case when participants are deceived about the study's actual hypotheses or when research is conducted in a naturalistic field setting. Researchers are also enjoined to establish and follow data and safety monitoring procedures. The well-being of their participants must be monitored at all times, and if any unforeseen negative consequences of the study arise, the researcher must intervene and minimize those risks. The data generated by the research process must also be safeguarded, particularly when the research deals with sensitive, personal topics or the disclosure of the participants' responses would subject them to legal prosecution or social harm.

In many research settings, investigators must also submit their research plans to impartial reviewers before they carry out their research. Often referred to as institutional review boards (IRBs), these panels ensure that researchers are complying with required standards for research involving human participants, including the required elements of informed consent, protection of pri-
vacy, and minimization of all risks. Such panels would be responsible for reviewing, for example, deception studies: those research projects in which the participants are not informed of the actual purposes of the study in advance. Researchers request a waiver of the usual requirement for complete and accurate informed consent only in rare cases when they feel that participants would respond differently if they were fully informed of the study’s purposes, and when they can provide clear evidence that the study will not harm participants in any way.

ETHICS AND SCIENCE

Social scientists, as members of the scientific community, strive to expand the knowledge of human behavior and apply that understanding for the enrichment of society and its members. But social scientists, as members of the larger social community, are also bound by norms that define what actions are considered moral and what actions are considered immoral. Researchers, in their quest for knowledge, cannot sacrifice the welfare of their participants in the name of maximizing the power of their research designs. The ethics guidelines that have emerged ensure that researchers’ studies will be both scientifically valid and ethically acceptable.

ETHNIC CONFLICT

Ethnicity culturally differentiates groups from one another based on each group’s prominent characteristics, including a common history, ancestry, language, as well as other kinds of symbols, dress, religion, and traditions. Ethnic affiliations do not necessarily fragment ethnically diverse societies but the context tends to influence how individuals organize and define themselves as well as how others regard them. Ethnic differences can generate ethnic conflict when these differences are used to promote prejudice and discrimination against a group that has been marked or stigmatized. Stigmatization of groups can occur within and between countries. It may manifest itself in various forms and to different degrees. But the pertinent literature diverges on the root causes of ethnic conflict, from riots to genocide. Broadly speaking there are two contending perspectives, the cultural and structural paradigm. Both perspectives implicitly or explicitly implicate the role of social institutions.

The cultural paradigm regards ethnic conflict as a social identity issue prompted by real or perceived threat to group boundaries and a familiar way of life. In this case resorting to group identity represents a fallback position for the frightened, alienated, and the angry as the ethnic group becomes the magna mater. Structural changes, for example, rapid, often imposed modernization or dramatic regime change, both accompanied by institutional failures, may evoke reactions expressed in cultural terms in triggering the closing of ethnic group boundaries.

The structural paradigm postulates that ethnic conflict is not about ethnicity at all but rather involves economic and political factors, including territory. Ethnicity may be manipulated to gain economic and political power, and for stratifying societies or nation-states within the world system. Stratification usually involves exploitation of the less powerful groups.

When diverse ethnic groups share a common territory they may resort to segregation as one type of ethnic conflict. Segregation inhibits a group’s contact with other groups, as was practiced in Europe, beginning in Venice, Italy, in 1516 with the confinement of Jews to areas of towns or ghettos. Other examples include blacks in the United States between the end of slavery and desegregation, and blacks in South Africa under apartheid. During World War II (1939–1945) the U.S. government confined Japanese Americans to internment camps. Generally, forced segregation renders the ghettoized group vulnerable to individual and institutionalized harassment by the other group and sexual relations between groups as well as intermarriage are punishable by law. One of the unintended consequences of segregation is for the forcibly isolated group to further accentuate its distinctive cultural characteristics. This is one area where race and ethnicity intersect. Segregation may avert ethnic riots, a type of ethnic conflict, which involves sudden, often brutal violence inflicted on members of one ethnic group by members of another ethnic group.

Expulsion is another strategy of ethnic conflict, when the dominant group forces a less powerful group to relocate. One historical example is that of European colonists in the Americas, who conquered territories inhabited by Native Americans, displacing the indigenous population from its ancestral lands. Another example is the case of the Palestinians, who were expelled from Israel to make room for the Jewish State in 1948. An additional case, rarely dis-
cussed although it constitutes the largest forced migration of modern times, is the expulsion of 14.5 million Germans from East Central Europe between 1944 and 1950. Expulsion is a type of ethnic cleansing. Usually the perpetrators want to achieve simultaneous goals: wipe the region clean of the expelled ethnic groups and decimate it in the process.

Ethnic conflict in the former Yugoslavia attracted world attention and international intervention largely because it involved ethnic cleansing. Yugoslavia had been under the iron fist of communism. With the demise of communism latent ethnic tensions erupted into open ethnic conflict in a civil war in 1991. Yugoslavia disintegrated as a nation-state, splintering into smaller states with populations of numeric majority and minority ethnic groups, some of which vied for political power. Croatia asserted state autonomy by forcibly expelling a substantial number of Serbs that formerly coexisted with Croats. The Bosnian conflict between Serbs, Croats, and Muslims erupted into a war in 1992. Serbs attempted to ethnically cleanse Bosnia of the Muslim population. Serbs’ strategies of ethnic cleansing involved the internment in concentration camps of large numbers of Muslim men, as well as their torture and murder, and the systematic mass rapes of their women. In addition to harassment, these are widely used practices of ethnic cleansers toward survivors of the targeted group, regularly accompanying expulsion. The former Yugoslavia also generated the 1999 Kosovo War, in which Serbs attempted to ethnically cleanse the province of Kosovar Albanian Muslims. Following NATO’s military intervention, the process of ethnic cleansing reversed itself; Kosovar Albanian Muslims turned on Serbs. The region has remained volatile despite new borders representing ethnic nationalism and the presence of a United Nations contingent.

The most extreme form of ethnic cleansing is genocide, the intent to systematically destroy an entire national or ethnic group. The term genocide was first applied to the attempted extermination of Jews by the National Socialists or Nazis in Germany. Millions of Jews and others deemed unfit or dangerous to Adolf Hitler’s regime were murdered in concentration camps during World War II, in the context of a well-orchestrated campaign of virulent anti-Semitic propaganda. History witnessed additional instances of attempted genocide, including the Turkish Ottoman Empire’s massacre of more than 1 million Armenians between 1915 and 1923, the killing fields of the Khmer Rouge in the 1970s where 2 million Cambodians perished, and the Hutu’s slaughter of the Tutsis during the 1990s in Rwanda, Africa. The structural school of thought views the Rwandan case as a class war instead of ethnic cleansing. Some regard the forced migration of 14.5 million Germans from East Central Europe, resulting in more than 2 million civilian deaths, and the fire bombing of Dresden at the close of World War II, additionally killing several hundred thousand civilians, as attempted genocide. Scholars disagree, however, on which cases besides the Jewish case constitute genocide.

If one applies the structural lens to the ethnic conflict in Iraq that erupted since the U.S. war on that country and the removal of Saddam Hussein’s dictatorial regime, one can explain the conflict between Shi’is, Sunnis, and Kurds as an attempt by elites to gain political and economic power by appealing to the respective ethnic group. The absence of strong institutions able to mediate exacerbates this conflict. Similar to the former Yugoslavia, each power broker tries to capitalize from long-standing tensions between the groups. The international context and external powers are implicated as well.

ETHNIC ENCLAVE
The term *ethnic enclave* first emerged in the contemporary sociological literature in 1967 (Hanna and Hanna 1967). However, Alejandro Portes and his colleagues (Portes and Bach 1985; Portes and Manning 1985; and Portes and Steppick 1985; but see also Model 1985) are credited with developing the concept theoretically and bringing it to the forefront in our understanding of the labor market experiences of marginalized workers, particularly immigrants. A review of the literature shows that while the ethnic enclave concept gained popularity during the 1985–1994 period, it continued to receive attention in the 1995–2005 period.
THEORETICAL ORIGINS OF THE ETHNIC ENCLAVE CONCEPT

The origins of the ethnic enclave concept can be traced to the segmented labor market perspective (Sanders and Nee 1987), which is an extension of dual economy theory (Averitt 1968; Galbraith 1971). According to this perspective, the labor market is segmented in advanced capitalistic societies into at least two labor markets (Edwards 1975; Gordon 1972). Primary labor markets are characterized by stable working conditions, high wages, scarce skill specifications, internal labor markets, and high returns to human capital investments for workers. In contrast, secondary labor markets are characterized by high turnover rates, low wages, low skills, lack of opportunities for promotion, and lower returns to human capital. Given that advanced capitalism requires the continual flow of low-wage and relatively unskilled labor to fill undesirable jobs (Burawoy 1976; Piore 1979; Sassen-Koob 1978), minorities, women, and immigrants are disproportionately clustered in secondary labor markets (Light and Gold 2000; Sanders and Nee 1987; Tolbert et al. 1980).

However, Kenneth Wilson and Portes (1980) shifted the focus from “ethnic” to “immigrant” enclaves in one of the earliest recalibrations of the ethnic enclave concept. Subsequently, Portes defined the enclave economy as involving “immigrant groups which concentrate in a distinct spatial location and organize a variety of enterprises serving their own ethnic market and/or the general population. Their basic characteristic is that a significant proportion of the immigrant workforce is employed in enterprises owned by other immigrants” (1981, p. 291).

Hence, Portes’s (1981) “immigrant enclave” concept has two characteristics: (1) a critical mass of immigrant-owned business firms that employ a critical mass of co-ethnic workers; and (2) spatial clustering of enterprises. Although Portes and his associates (Portes and Jensen 1992; Portes and Bach 1985) have altered the definition, it has basically followed the general conceptualization of immigrant enclaves.

The term ethnic enclave economy has come to stand for the economic advantage of location clustering (Light and Gold 2000). Some argue that one of the benefits of ethnic enclaves is protection from discrimination (Portes and Bach 1985; Zhou 1992). Accordingly, ethnic enclaves allow workers from discriminated groups to overcome the barriers for which they are punished in mainstream labor markets. As such, the process of ethnic enclave formation compensates for background deficits and discrimination that ethnic groups encounter in the general labor market. Examples of successful groups in ethnic enclaves include Japanese Americans in the early twentieth century (Bonacich and Modell 1980) and Cubans in contemporary Miami (Portes and Jensen 1992).

In contrast, some argue that ethnic enclaves are used to maintain and enforce sweatshop conditions, including low-wages and restrictions against union organizing (Sanders and Nee 1987). Additionally, ethnic enclaves may fuel paternalistic ethnic assistance in which immigrants who depend on kinship or ethnic-group assistance in the initial stage of adaptation to a host society may become caught in a web of obligations that interfere with rational pursuits of economic opportunities (Li 1977). Furthermore, as long as immigrant and minority workers are restricted to ethnic enclaves, entrepreneurs can profit from the surplus of cheap labor (Schrover 2001) and impede upward mobility by restricting the accumulation of skills (e.g., proficiency in English) to compete in general labor markets (Sanders and Nee 1987). Indeed, in a study of Cuban and Chinese immigrants, Jimmy Sanders and Victor Nee (1987) observed that the positive economic rewards of the ethnic enclave apply only to entrepreneurs but not to their workers.

In sum, immigrants, and their native-born counterparts to a lesser extent, participate in ethnic enclaves because of their limited human capital, their exclusion from mainstream labor markets, and as a protective mechanism from discrimination. However, there is no agreement about the benefits of these ethnic enclaves, particularly in light of the characteristics often associated with them—unsafe working conditions, low-wages particularly for rank-and-file laborers, workers being overburdened with obligations, and the entrapment of workers that impedes their acquisition of the human-capital resources needed to gain greater economic rewards.

**ETHNIC ENTERPRISES**

Ethnic enterprises, which often result from voluntary or involuntary segregation or segmented economic systems, are economic entities tied to specific cultural groups. They provide goods and services both within and external to the specific group. Ethnic enterprises that are associated with ethnic communities provide avenues for social mobility, socialization, and acculturation for group members. There are several factors, occurring both internal and external to the specific community, that account for the viability of ethnic enterprises. For example, among some immigrant communities (such as Koreans), ethnic enterprises appear to be more vibrant and produce significantly higher rates of self-employment than in the rest of the United States. Alternatively, some racialized groups, such as blacks, appear to have markedly lower rates of enterprise viability and self-employment.

The success or failure of ethnic enterprises cannot be viewed in a vacuum. The road to success has much to do not only with entrepreneurial skill and motivation, but also with the business climate in which the enterprise operates. The relative success of Koreans in the United States, for example, had a lot to do with the U.S. government’s influence in creating cheap labor in South Korea, the economic interests of the South Korean government, the decline of U.S. labor standards, and the positive response of U.S. corporations to Korean small business development. As pointed out by Ivan Light and Edna Bonacich, in *Immigrant Entrepreneurs* (1988), business enterprises among Korean immigrants were positively influenced by a decades-long international process that was stimulated by U.S. governmental policies encouraging the development of capital, technology, and military power in Korea. The ability of Korean businesses to take advantage of these external stimuli was greatly influenced by their use of kin labor networks and the traditional Korean revolving credit association, or "kye." Thus, external and internal factors produced a situation that enhanced the viability of Korean ethnic enterprises. With time and success, the Korean economic sphere grew beyond their enclave economy. However, other ethnic and racial groups have at times responded to the Koreans’ success with antagonism. Consequently—as exemplified by the 1992 Los Angeles riots, in which several Korean businesses were targeted—such success is not without its costs.

Similar positive results have also been witnessed among Japanese and Chinese immigrant enterprises. One should not, however, assume that their immigration experience has not been fraught with significant loss, nor should one look upon these success stories as indicative of the failure of other groups. The experiences of some groups, such as blacks, have been drastically different, suggesting alternative (and often negative) development. The
involuntary migration of blacks, followed by centuries of oppressive slavery, racial segregation, and an economic system hostile to black economic development, has severely restricted the development of African American enterprise.

Nonetheless, a continual record of black enterprise development can be identified in the United States from as far back as 1736. Significant developments have always been associated with external and internal factors. For example, in both the Revolutionary War and the Civil War, black business flourished as a direct result of blacks taking advantage of enhanced business climates in the U.S. The 1920s, for example, is often described as the golden era for black business development. Over 100,000 black business enterprises were observed by 1932. Another period of black economic success followed World War II, and a final boom in black enterprise development was associated with the 1960s civil rights and affirmative action initiatives. Thus, by 1969, approximately 1,603,000 black enterprises, generating annual receipts of $4.5 billion dollars, were concentrated in five states (California, Illinois, New York, Ohio, and Texas). The leading businesses, in terms of revenue, were automotive dealers, service stations, and food retailers. These successes belie the hardships, setbacks, and failures along the way.

As pointed out by Manning Marable, both dominant corporations and the public in the United States have met each period of black business success with significant retrenchment, racial hostility, and racially exclusionary practices. Vandalism targeting black enterprises occurred during and immediately after each of the above periods, leading to a significant decline in black businesses in each instance. In 1919 alone, twenty-six race riots were identified. In cities like Tulsa, Oklahoma, and Cincinnati, Ohio, blacks were uprooted and forced to leave.

Another example occurred in California in association with the gold rush of the mid-1800s. Originally, blacks were encouraged to develop a wide range of businesses. But with the eventual decline of opportunities, white racial preferences began to restrict black business operations to the service trades, such as tonsorial, bootblack, livery, restaurant and catering, and drayage businesses. Blacks restricted to the tonsorial trade developed a monopoly. This monopoly however was short-lived, as white patrons began expressing a preference for white barbers. Restrictive ordinances, city covenants, real estate and business redlining, and racially exclusionary business and labor practices served to curtail black enterprise development from 1910 to the mid-1960s. The 1960s civil rights movement, and its associated affirmative action programs, marshaled in what many thought would be a new day for black business development. This fifteen-year period, unprecedented in U.S. history, witnessed the development of a large, diverse middle class working in the public sector. Accompanying this was the growth of a new black elite in such areas as media, politics, sports, and entertainment.

Conservative backlashes to the civil rights movement, starting in the mid-1980s, served to stymie black economic enterprise development in the black community. These conservative backlashes took the form of (1) conservative attacks against affirmative action, (2) continual bias in banking and lending programs, and (3) a reluctance on the part of corporate America to fully encourage or utilize products and services.

Contrary to popular belief (or mythology), white ethnicity is alive and well in America. While the illusion of a monolithic white world serves specific political and cultural purposes, the reality of specific white enclaves serves very real and continuous economic needs. Thus, white ethnic enterprises associated with Italians, Irish, Germans, Poles, Jews, and others are easily identifiable throughout the United States. Throughout much of America, major white ethnic holidays not only celebrate white ethnicity but also tend to feature white ethnic enterprises. Such ethnic celebrations include Oktoberfest (German), St. Patrick's Day (Irish), and Columbus Day (Italian), though the fact that these celebrations take on a national character does much to hide the fact that they are indeed ethnic in nature. Since the 1960s, a tremendous amount of scholarship has been produced documenting the emergence and the continuance of ethnic communities and identity—as well as the resultant white ethnic enterprises.

White ethnic communities persist because they continue to provide for the special needs of specific communities. The principal ways in which these needs are satisfied are through the perpetuation and creation of ethnic enterprises. While these enterprises and communities were once located mainly in urban areas, they are now also associated with suburban growth. What this suggests is that as these white ethnic communities gave way to urban migrants, they were able to continue their existence in suburbia.

The economic viability, diversity, and independence an ethnic enterprise enjoys is dependent upon such things as the perceived status of the immigrant community in the host society, the availability and types of financial resources, and the size, longevity, and history of the ethnic group (and other ethnic groups) in the host society. Larger and more financially secure ethnic enterprises are typically able to operate more independently of a particular ethnic community. Alternatively, smaller and less financially secure enterprises are more likely to be dependent upon constituent ethnic communities for survival. For these latter types, growth and development of ethnic enterprises
are more likely to be dependent upon the capacity of the ethnic entrepreneur to accumulate start up capital.

Postcolonial situations may provide the most fertile environments in which unique hybrid ethnic enterprises can develop. Richard Werbner documented this hybridism in Botswana in the early years of the twenty-first century. He calls it a “cosmopolitan ethnicity” that “builds inter-ethnic alliances from intra-ethnic ones and constructs differences while transcending it” (Werbner 2002, pp. 731–732). This approach maintains traditional intra-ethnic identity while also seeking to identify with a national ethnic elite identity. Such transcendence is most appropriate in those situations in which an ethnic elite is able to promote a set of national economic and political agendas through its various enterprises. Thus, the Kalanga elites, originating in the borderland of Botswana and Zimbabwe, are able to utilize a form of super-tribalism to foster nation-building in Botswana.

Although ethnic enterprises facilitate the economic stability of ethnic elites in specific host countries, they may also facilitate the economic stability of the countries of origin. By tracking remittance and capital flow data to developing countries, researchers have demonstrated that these transfers can mean the difference between economic stability and financial crisis. Billions of dollars go from primarily Western host countries to developing countries in the form of remittances. (Remittances to developing countries were estimated by the World Bank to be US$72 billion in 2001 and US$93 billion in 2003, which was significantly higher than the global foreign aid in those years of US$52 billion and US$69 billion, respectively.) Between 2001 and 2006, such remittances doubled, as countries became more aggressive in documenting and encouraging the transfer of funds. Unfortunately, activities that may account for even more transfers—illegal drugs and organized crime—often still go under the radar. Regardless, such remittances provide the basis of considerable reinvestment, capital transfer, and economic investment in third world countries. While Latin America (specifically Mexico) accounts for the largest share of such remittances, the amount going to Asia, the Middle East, Israel, and Africa cannot be discounted.

ETHNIC FRACTIONALIZATION

Ethnic fractionalization (EF) deals with the number, sizes, socioeconomic distribution, and geographical location of distinct cultural groups, usually in a state or some otherwise delineated territory. The specific cultural features might refer to language, skin color, religion, ethnicity, customs and tradition, history, or another distinctive criterion, alone or in combination. Frequently these features are used for social exclusion and the monopolization of power.

A crucial distinction is whether there is a commonly accepted value order above each distinct subculture (as in the "melting pot" idea) or each culture stands for itself (the "salad bowl" image). In addition one culture may be dominant in a relatively benign way (as in the British and Roman Empires, which had second-class citizens but with access to some public goods) or in a harmful way (the Tutsis and Hutus reciprocally, the Germans and Poles or Czechs, the Russians and the peoples in Caucasus and the Baltic States).

The distinction between majorities and minorities is important, though frequently some minorities are better off socioeconomically (Basques, Jews, the Indians in East Africa, the Chinese in Southeast Asia) or even rule over majorities. The conflict potential due to EF increases if disputed borders are involved (as in irredenta) or if the state collapses (as in sub-Saharan African examples) or does not exist at all (Palestine, the Kurdish state). Then there is a temptation either to exit into the other bordering state or to attack from there (Carment and James 2004).
Because ethnic or other cultural minorities often have suffered from other (majoritarian) groups in the past, they have vivid memories of their tragedies and fears for the future. Structurally they cannot trust the state as a benevolent mediator because there is always the possibility that it might command private information (information withheld from the opponent) to be used against the subgroup, thus wiping out any consociational arrangements. Such arrangements (as in Switzerland, the Netherlands, the European Union) usually follow the proportional rule of representation and engage in broad-based collective decision making. In cultural matters (e.g., language use, schooling, cultural symbols) there is even allowance for veto rights by cultural subgroups. Yet few of these arrangements have survived (Lijphart 1977).

All variations in numbers and sizes of EF seem possible. In theory two large groups equal in size could balance each other perfectly (consider the Israelis and Palestinians) or could provide ground for perennial self-reinforcing conflict. Likewise a small number of groups of equal size could balance each other but also provide sources of intergroup conflict, particularly if coalitions are considered (the tertius gaudens phenomenon, that is, the third party that is winning from a conflict of the other two parties). “Measures of polarization are more appropriate to capture the intensity of disagreements across groups” (Alesina et al. 2003, p. 164), reaching their maximum when two equally sized groups confront each other.

Three basic arguments explain how and in part why ethnic heterogeneity creates a potential for social cleavage and conflict. First, following Georg Simmel (1908), the “stranger” is considered untrustworthy and in possession of hidden knowledge. He or she can compare his or her past knowledge and experiences with his or her present ones. He or she comes from unknown places and may leave for unknown ones. In knowing less about the local rules and values, he or she intensifies we and they feelings, which carry mostly negative and threatening stereotypes. Second, group experiments show that these distinctions arise even when characteristics differ minimally (see minimal group theory, Tajfel 1981). Third, cultural groups reduce social costs within groups in daily interactions (with lower rates of misunderstanding and conflict), they give protection, and they produce a public good of shared norms. On this basis, EF will persist. Thus Michael Hechter (2000) recommends granting autonomy to distinct cultural groups and shunning centralism. Cultural autonomy and decentralization can buy off conflict. The paradigm at the macro and micro levels is the Roman Empire or the Islamic millet system.

When identities become politically salient in an ethnically diverse area can be explained (partially) by a number of theories, the most prominent being resource mobilization theory, which stresses entrepreneurism on the part of leaders and resource accumulation and collective action on the part of followers (Tilly and Tarrow 2006); relative deprivation theory; and more directly to the timely circumstances, the theory of political opportunity structure, which, for example, involves the collapse of a repressive multicultural empire such as the Soviet Union with ethnic strife in the Caucasus and the Baltics, external warfare, and shelter with groups beyond the national border (Carment and James 2004).

Karl Deutsch (1966) adds an important macro perspective, emphasizing that modernization of one ethnic-cultural group usually leads to more integration via social mobilization. In case of different ethnocultural groups, however, massive conflict results, paradoxically at higher levels of overall economic development. In each subgroup, social movement entrepreneurs employ the forces of communication and indigenous integration for the benefit of cultural distinction (e.g., in Northern Ireland, Palestine, and Iraq). Forms of conflict resulting from EF include coups d’état, interethnic rioting and war, and even external warfare (Hibbs 1973; Carment and James 2004). States that have suffered from violent ethnocultural fractionalization and conflict usually exhibit lower overall levels of socioeconomic development and attract little foreign investment (Collier and Hoeffler 2004). The breakdown of the state monopoly of violence and territorial borders looms large, contributing to and ending in state failure (Rotberg 2004).

EF usually is measured as 1 minus the Herfindahl concentration index of ethnolinguistic group shares, which reproduces the probability that two randomly drawn individuals from the population belong to different groups. The theoretical maximum of EF at 1 means that each person belongs to a different group. Alberto Alesina and colleagues (2003) employ this measure separately for ethnic, linguistic, and religious fractionalization (with data mainly from the Encyclopedia Britannica). EF correlates negatively with economic growth and government quality (from 1960s onward, n=190 countries), although its effects decline with intermediating channels, such as schooling, financial depth, fiscal surplus, and the use of telephones controlled (Easterly and Levine 1997). According to Alesina: “The thirteen most ethnically diverse countries are all in Sub-Saharan Africa, followed by Yugoslavia and seven more Sub-Saharan African countries. The least ethnically fractionalized countries are South Korea, Japan, and North Korea” (Alesina et al. 2003, p. 163).

EF may, however, be endogenously affected, for example by changes in different group fertilities, by the definition of groups, and by individual self-definitions. James Fearon and David Laitin (1999) point to reverse causalities (e.g., cases of rebellion leading to the inclusion...
of groups in the dataset or large-scale ethnic violence causing low gross domestic product (GDP) in suggesting improvements in the minorities at risk data (Gurr 1993), another of the major datasets on EF. Groups included in countries with more than one million inhabitants and comprising at least 1 percent of the population had to meet at least one of four “risks”:

the group suffers “discrimination”;
it is “disadvantaged from past discrimination”;
it is an “advantaged minority being challenged”; or
the group is “mobilized,” meaning that “the group (in whole or part) supports one or more political organizations that advocates greater group rights, privileges, or autonomy.” (Gurr 1993, pp. 7, 65)

Fearon and Laitin provide numerous examples of dubious classifications on the basis of language or culture alone. The third and oldest measure is the ethnolinguistic classification from the Soviet Atlas Narodov Mira (Atlas of peoples of the world, 1964), which relies on linguistic distinctions and thus obscures other aspects of ethnicity, such as racial origin, skin color, and cultural traits (see Fearon 2003 for a further dataset).

Fearon and Laitin also report results on geographic concentration, “with widely dispersed and mainly urban groups being unlikely to be involved in ethnic violence”; on relative group size, “with a weak tendency for larger groups to be more disposed to violence”; and “degree of ethnic heterogeneity of the country, with greater heterogeneity associated with less violence once we control for GDP and other factors” (Fearon and Laitin 1999). Intermixing as such, and thus the alleged “security dilemma” (Posen, in Cederman 2002), is not enough to dispose ethnic groups to violent conflict.

The question remains why are some minorities engaged in large-scale separatist or autonomy-related violence while others are not? “Ecological” data must be supplemented by perceptual data on the deepness and unbargainability of conflict to go further in explaining the virulence of EF and participant groups and to avoid the logical pitfalls of sampling on the dependent variable.

ETHNICITY

Ethnicity refers to the differentiation of groups of people who have shared cultural meanings, memories, and
descent produced through social interaction. In classical Greek, the terms *ethnos* and *ethnikos* were used in a number of ways to refer to a collectivity that shares similar cultural or biological characteristics—for example, a tribe of people or a band of friends—and who were not Greek, came from outside the nation, were foreign and different, and were also considered inferior, barbarian, and less civilized. This distinction between ethnically marked “others” and nonethnically marked “us” persists in modern popular usage with references to ethnic fashion or food.

Sociological accounts of ethnicity are highly varied but tend to break the classical linkage between ethnicity and “other” in asserting that all people are ethnically located in that their subjectivity and identity are contextualized by history, language, descent, and culture. Ethnicity usually refers to the differentiation of social groups on the basis of the following distinct criteria. First, a notion of a “homeland” or place of common origin is a key element. It is often linked to the idea of a diaspora, where an ethnic group has migrated from the homeland to form communities elsewhere whose members identify with their place of origin. Second, a common language, either distinctive in itself or a distinct dialect of a language shared with others, may be central to the construction of shared memories and affective belonging. Identification with a distinct religion—for example, Sikhism—or a religion shared with others can be a central feature of many ethnic groups. A common culture with distinctive social institutions and behavior, diet, and dress, as well as a common tradition or shared history of one’s own “people” or nation are other criteria used in specifying ethnic groups.

Ethnicities may be highly durable over millennia and space, and they can also be formed from new conjunctions of social contexts. This occurs, for example, when migrants shape a new backward-looking sense of ethnic belonging with the construction of national context to produce hyphenated forms, such as British-Asian or Hispanic-American. Ethnic solidarity can provide a deep sense of physical and psychological security, allowing individuals to identify and find a sense of common purpose with a great and long-lasting tradition of people. But if fictive shared beliefs underlie ethnic differentiation, then the boundaries of ethnic groups are inevitably unclear and caution is required in assessing the extent to which external categories accurately reflect social meanings, social roles, and wider social inequalities. There may often be a poor fit between the state and bureaucratic constructions of ethnic categories and dynamic forms of intersubjective ethnic identities.

Scholars have made various attempts to develop global typologies of ethnicity, including those by Thomas Eriksen (1993) and Stephen Castles (2000). These typologies include indigenous peoples dispossessed and overwhelmed by colonizers. The United States, Canada, Australia, and New Zealand have similar histories in this respect and contain indigenous minorities—Aborigines, Maoris, Native Americans, and Native Canadians—who remain in unequal marginalized positions. Indigenous groups are also found in Latin America, where there have been massacres, for example, in Guatemala in the 1980s, and in most Asian countries, where native groups may be categorized as “tribal peoples” or “hill tribes” (Castles 2000). Other categories and contexts include: migrant workers and their descendants forming strong ethnic communities—for example, Turks in Germany or Pakistanis in the United Kingdom; ethno-nations—for example, the Quebecois in Canada or the Basques in Spain—with regional ethnic groups contesting national control; postslavery groups in, for example, Brazil, the United States, and the Caribbean; and people living in postcolonial and postcommunist contexts, as in, for example, Uganda, Zimbabwe, Chechnya, or the former Yugoslavia, where ethnic loyalties have had grave consequences in terms of conflict and violence.

UNDERSTANDING ETHNICITY

Ethnic hostility, discrimination, and exclusion take many forms, but three broad categories can be identified. The first category includes the most severe acts involving mass societal aggression, such as the annihilation of native peoples in North America, South Africa, and Australia from the seventeenth to the twentieth centuries; the Nazi Holocaust during World War II (1939–1945); plantation slavery from the late seventeenth to the mid-nineteenth centuries; or the massacres of Tutsi by Hutu in Rwanda in 1994 and ethnic cleansing of Kosovan Albanians by Serbs in the 1990s. The second category of ethnic exclusion and discrimination involves denial of access to societal opportunities and rewards in such areas as employment, education, housing, health care, and justice. Many instances of such discrimination have been documented in Europe by the European Monitoring Centre on Racism and Xenophobia, mostly affecting Roma, Sinti, Gypsy, and Traveller groups. Poor mental and physical health, lower levels of educational attainment, restricted access to work, and lower income levels have been linked to poor housing conditions for many of these groups. The lack of social rights has also constrained their opportunities for political participation. A third category of ethnic discrimination includes the use of derogatory or abusive language or forms of representation that are felt to be offensive (e.g., the anti-Muslim Danish cartoons that circulated in 2005 and 2006). Such derogatory expressions, together with racist jokes, the use of Nazi insignia, and unwitting stereotyping and pejorative phrases, may constitute lesser forms of ethnic hostility. Explanations for ethnic conflict must
encompass micropsychological processes, individual and group experiences, and competition and socialization, together with structural power relations and aspects of globalization.

Sociological approaches to conceptualizing ethnicity fall into two camps. Primordial approaches, first suggested by Edward Shils in 1957, regard ties of blood, race, language, region, and custom as exterior, coercive, and given. This approach has been criticized as static and naturalistic, and as failing to account for the impact of immigration and intermarriage. In contrast, instrumentalist approaches, represented, for example, by Michael Banton’s work on ethnic competition (1993), view ethnicity as a social, political, and cultural resource that can be used in competition for resources or as a motivation for conflict. This approach has been criticized for underplaying durable, affective, and persisting constructions of ethnic identity. The transactionalist mode of enquiry advocated by Fredrik Barth is seen as making a vital contribution to the instrumentalist approach in arguing that “the critical focus of investigation from this point of view becomes the ethnic boundary that defines the group, not the cultural stuff which it encloses” (Barth 1969, p.15).

The conceptual separation of culture and ethnicity and the focus on processes of interaction and boundary-maintenance have been highly influential.

As with culture, the concepts of race and nation crosscut the specification of ethnicity. As Steve Fenton (2003) has argued, the word nation also refers to groups of people with common descent, culture, and a shared sense of territory. But what differentiates a nation from an ethnic group is its members’ construction as a state or a state-like political form. Also, ethnic groups are more frequently conceived as a subset of the nation-state, particularly where states do not have a pure monoethnic form. The word race also refers to groups with a common descent and culture, but race carries an explicit reference to physical or visible difference. Race may operate as a subset of ethnicity, being one of the many markers used to differentiate a particular ethnic group. On the other hand, ethnicity may operate as a subset of a race, where one racial group is seen as encompassing many ethnic groups—for example, the community of black British within which Caribbean ethnicities have been erased.

Competing sociological accounts of ethnicity have been classified and critically differentiated by Siniša Malešević (2004). Classical sociology, neo-Marxism, functionalism, symbolic interactionism, sociobiology, rational-choice theory, elite theory, neo-Weberian approaches, and antifoundationalist positions have all been used to theorize ethnicity. Malešević illustrates how each position can be used to provide an explanation of the 1994 Rwandan genocide, and he highlights key epistemological tensions.

Differing approaches prioritize different determining factors, ranging from the legacy of German and Belgian colonial divide-and-rule policies in the region; the downfall of the Rwandan economy; the lack of a common cultural system; the primordial ethnic differentiation between shorter, darker Hutus and taller, light-skinned Tutsis; the individual self-interest of those involved; the motives and behavior of Hutu power holders; status differentiation between Tutsi aristocracy and Hutu farmers; and the rationalist urge to impose order on difference using modernist methods. Central factors in such cases also include, as Helen Fein (1993) has argued in relation to Armenian genocide during World War I (1914–1918) and the Nazi Holocaust, the rise of new elites in declining states who see their idealized political vision as exclusive and who position minorities as outside moral obligation, and where extermination is less visible and operates with little fear of sanction.

**ETHNIC RELATIONS**

Ethnic relations encompass highly varied, complex forms of social relations where attachment to cultural difference is paramount. Milton Esman (2004) has identified differing categories of ethnic relations. Exclusionary domination involves enforcing an ethnically stratified system of unequal rights, status, and opportunities. This was common in European colonial societies on all continents, in apartheid-era South Africa, and in many of the more extreme cases previously noted. Inclusionary domination or assimilation involves dismantling ethnic cultures, languages, and attachments by facilitating acculturation to the nation. The classic French republican model of aggressive assimilation, the Dutch government’s approach to its Chinese minority, and the Turkish government’s approach to Turkey’s large Kurdish minority are all examples of this form of ethnic relations.

Granting rights to minority groups can also ensure their domination. Limited rights have been granted to Arab Palestinian citizens in Israel, but these rights serve to confirm their second-class status, and there remains entrenched opposition to equal rights with Jewish Israelis. In Malaysia, domination with significant but unequal rights for Chinese and Indian citizens is well established. Power-sharing solutions have been developed in many national contexts where ethnic divisions have not produced conflict or separation. Belgium, India, and Switzerland provide examples where forms of federalism and consociationalism have enabled the establishment of multiethnic states. This approach supports ethnic pluralism, while the final position, integration, foresees its decline with the gradual building of social and cultural cohesion. This position is strongly advocated in the United Kingdom, where multiculturalism was officially
Ethnocentrism

Ethnocentrism is a basic attitude expressing the belief that one's own ethnic group or one's own culture is superior to other ethnic groups or cultures, and that one's cultural standards can be applied in a universal manner. The term was first used by the American sociologist William Graham Sumner (1840–1910) to describe the view that one's own culture can be considered central, while other cultures or religious traditions are reduced to a less prominent role. Ethnocentrism is closely related to other attitudinal indicators for racism, xenophobia, prejudice, mental closure, and, more generally, an authoritarian personality structure. Ethnocentrism is widely used in research on social and political attitudes because it proves to be a very powerful and easily identifiable attitude that can be measured in a valid manner with a limited number of variables. Although ethnocentric prejudice can be directed toward one specific outsider group, empirical research reveals that usually ethnocentrism is generalized toward all outsider groups.

Although ethnocentrism is closely related to racism, it can be distinguished from racism because it does not involve necessarily a negative vision toward other races. Any culturally distinct outsider group (whether the distinction involves language, religion, color, or descent) can be targeted by ethnocentric attitudes. In practice, European researchers often tend to avoid using the term racism because they are reluctant to apply the concept of race to human beings. In a U.S. context, the use of the term racism is not considered a problem. Given the fact that ethnocentrism is such a powerful attitude and is associated strongly with various behavioral patterns, ethnocentrism measurements are routinely included in almost all major survey projects. Ethnocentrism leads to in-group favoritism with regard to contact and cooperation, and accompanies outsider-group hostility, sometimes even leading to intergroup conflict, violence, or support for discriminatory behavior. There is also an abundant research literature on consumer ethnocentrism, that is, the tendency of consumers to prefer goods and services produced in one's own society.
CAUSES OF ETHNOCENTRISM

Various explanations have been suggested for ethnocentrism. Social identity approaches assume that ethnocentrism is the result of a strong identification with the in-group of the actor, which almost automatically leads to negative feelings toward and stereotyping of members of the out-group. Because some personality types are more clearly dependent on this strong form of group identification, these personality types are also more vulnerable to adopting ethnocentric prejudice. Experimental research has demonstrated that even if groups are assigned on a purely random basis, processes of in-group identification and polarization with outsider-group members still occur.

Social scientists also have speculated that a lack of real-life contact with members of outsider groups might enhance stereotyping, as the outsider group can be seen as homogeneous, but the empirical evidence about the allegedly beneficial effects of contact tends to be mixed.

Realistic conflict theory, in contrast, assumes that ethnocentrism is triggered by a real or perceived conflict between various ethnic groups competing for scarce resources in society. The originally dominant groups in a territory will develop antagonistic feelings toward newly arriving outsiders when they perceive these outsiders as a threat to their own social position (e.g., in the labor or housing markets). In practice, however, empirical research has demonstrated quite convincingly that even groups whose positions are not threatened by ethnic competition still develop ethnocentric prejudice.

Survey research routinely reveals strong individual-level determinants of ethnocentrism: for example, high education levels effectively reduce ethnocentrism, and in general, men are more willing to express ethnocentrism than women. It is believed that actors with fewer individual resources (e.g., lower socioeconomic status, cognitive ability, or self-esteem) are more dependent on in-group confirmation of their identity, thus strengthening prejudice toward members of outsider groups. There is no consensus, however, on the impact of religion on ethnocentrism. Several authors have argued that this relation can be considered as curvilinear, with the highest ethnocentrism levels among believers that are only marginally connected to organized religion. Ethnocentrism is also clearly associated with distrust and with authoritarian and right-wing ideologies, and is the single most powerful determinant of extreme-right voting behavior.

ELEMENTS OF ETHNOCENTRISM

Research distinguishes two major components of ethnocentrism that are closely related but still can be empirically distinguished. Cultural ethnocentrism finds its origin in the belief that one’s own cultural norms and attitudes are superior to the cultures of other societies or groups. Furthermore, cultural ethnocentrists believe that this cultural order is threatened by the arrival of new groups (with their own cultural norms) to the territory that is claimed as their own. Cultural ethnocentrism often expresses itself in a symbolic manner, for instance, in disagreements about the public presence of cultural markers of identity such as clothing, religious symbols, or other visible elements of minority cultures. Economic ethnocentrism is tied more closely to the perception that other groups can be seen as economic competitors and therefore should be limited in their capacity as economic actors. Economic ethnocentrism can express itself in discriminatory measures on the labor market, and in boycotts or other consumer actions expressing a clear preference for goods and services associated with one’s own culture.

Some researchers have also distinguished between explicit and implicit ethnocentrism. In the explicit condition, respondents are willing to express negative stereotypes toward outsider groups; the implicit condition is characterized by an inhibition to express these sentiments despite the fact that other responses clearly indicate that the respondent is unwilling to grant the same rights and legal protections to members of outsider groups. Implicit ethnocentrism can lead to calls for segregation with regard to education, housing, or cultural participation, or to a negative attitude toward affirmative action.

Although throughout the world, various government agencies and education systems have developed social and legal strategies to reduce ethnocentrism, thus far no universally successful strategies have been documented. Avoiding stereotyping seems to be a necessary prerequisite, and mass media and other socialization agents clearly play an important role in this respect.

ETHNO-EPIDEMIOLOGICAL METHODOLOGY

The term ethno-epidemiology has acquired two different but intertwined meanings in the social sciences. On the one hand, it refers to an emergent cross-disciplinary health research methodology that combines the strengths of direct participant observation and other qualitative methods for understanding social meanings and contexts as practiced in medical anthropology with the design, sampling, data collection, and analytical strategies focusing on risk factors and disease outcomes developed in epidemiology. This use is referred to here as ethno-epidemiological methodology. On the other hand, as Michael Ágar notes in “Recasting the ‘Ethno’ in ‘Epidemiology’” (1996), the term is also used in the literature to refer to *emic* (i.e., insider) or folk systems of disease understanding and response. This usage is referred to as the ethno-epidemiological explanatory model. Together, these constitute important tools for conducting and targeting public health research.

ETHNO-EPIDEMIOLOGICAL METHODOLOGY

When medical anthropology emerged as a field, it was concerned primarily with folk illness conceptions and related indigenous healing behaviors. On this foundation, it has evolved into a robust subdiscipline focused on studying the immediate cultural and broader social factors involved in the experience, understanding, and behavior of illness. Medical anthropologists use this information to contribute to empirically grounded public health development. Epidemiology developed as the scientific arm of public health centered on emergent disease causation, trends in disease occurrence, and assessment of the effectiveness of intervention. Since the mid-1970s, the boundary between medical anthropology and epidemiology has witnessed a growing number of conceptual and programmatic exchanges. Some contacts have been fraught with tensions, as occurred in the medical anthropological critique of epidemiological construction of “risk groups” in the HIV/AIDS epidemic, or when epidemiologists express wariness about small, nonrepresentative anthropological studies. Other points of contact have been highly collaborative and productive, such as various successful oral rehydration projects internationally. Although both disciplines bring a distinct approach to the study of the intersection of disease and behavior, epidemiology traditionally has taken the formal road of statistical and quantitative methods, whereas medical anthropology has favored qualitative strategies that allow access to on-the-ground behaviors and insider understandings. Ethno-epidemiological methodology is a direct product of efforts to build collaborative approaches between these two health-related research disciplines.

The development of ethno-epidemiological methodology reflects several trends in public health and medical anthropology, including: (1) a growing reliance on mixed-method research designs and multidisciplinary research teams in the investigation of health risks; (2) an increasing emphasis in medical anthropology on systematic data collection and analytic strategies and a corresponding decline among quantitative researchers in criticism of ethnography as being unscientific; and (3) a growing understanding of strategies for the triangulation or integration of different types of data. All of these changes are seen, for example, in the study of drug-related risks for the spread of HIV disease. Research in this arena now typically involves teams of experts from diverse disciplines; the integration of ethnographical, epidemiological, and other approaches to data collection; and achievement of enhanced outcomes based on the comparison of qualitative and quantitative findings.

More recently, there has been a push for an even greater integration of medical anthropology and epidemiology through the creation of cultural epidemiology. According to Jim Trostle (2005), cultural epidemiology promotes the study of diseases and their causes in terms of the contribution to health trends made by culture. Modeled after social epidemiology, which examines the health-related effects of social inequalities, cultural epidemiology would extend the variables under consideration to include folk systems of disease classification, meaning systems, culturally constituted risk patterns and conceptions, and other behaviors commonly analyzed as cultural in origin by medical anthropologists. These factors, Trostle maintains, should be critically important to epidemiology because people’s conceptions and behaviors impact their health. Raymond Massé (2001) introduced the term critical ethnoepidemiology to refer to the linking of an interpretivist analysis of local illness meaning and a critical analysis of asymmetric social and economic relationships.

ETHNO-EPIDEMIOLOGICAL EXPLANATORY MODEL

Arthur Kleinman (1980) introduced the term explanatory model to label the ideas activated during an episode of sickness and treatment by all those involved in the clinical process. Explanatory models provide culturally meaningful explanations of sickness (e.g., its nature and causes) and treatment (e.g., best practices) that are used in health decision-making. For example, in *The Spirit Catches You and You Fall Down* (1997), Anne Fadiman recounts the story of Lia Lee, a Hmong child who began having intense seizures,
which were interpreted as signs of “soul loss” by her parents and a Hmong shaman, but diagnosed by physicians as epilepsy. Convinced that Lia’s parents were not administering the medicines they prescribed because of their faith in Hmong ethnomedicine, Lia’s doctors launched a successful effort to have her removed to foster care.

As Kleinman recognized, different parties active in a sickness incident—including professional healers, folk healers, and the wider social group of the patient—can embrace differing conceptions or models of illness, treatment, and recovery. Of interest to Kleinman, and many medical anthropologists ever since, are the relationship of explanatory models to the wider cultural systems of which they are a part and the nature of the interactions that unfold when alternative explanatory models meet (and perhaps clash) during sickness episodes in diverse socio-geographic settings.

Ethno-epidemiology in this sense, as an indigenous explanatory model of disease causation, spread, prevention, and treatment, reflects the growing medical and public-health understanding of the significant influence of patient attitude, experience, and behavior in sickness and recovery. D. Lee and coworkers (2004), for example, demonstrated that the Chinese cultural practice of peiyue—a postpartum custom of mandated family support—is associated with a lower risk of postnatal depression.

The two meanings of the term ethno-epidemiology described above are unified in their recognition of the fundamental importance of culture in health, with ethno-epidemiological methodology referring to approaches for its in-depth and systematic study, and ethno-epidemiological explanatory models labeling the local cultural conceptions of disease now recognized as a significant influence on disease expression and response.

ple, focusing on smaller environments and more intimate interactions.

Given the unique nature of ethnographic research, which distinguishes it from impersonal archival work, mass-administered questionnaires and number crunching, public surveillance, and more remote ways of interpreting people’s behaviors and their meanings, many fields and diverse interests have become attracted to ethnography, from corporations and market research firms to other disciplines in the social sciences and the humanities. Although ethnography is associated with anthropology primarily, there is an important tradition of ethnography in sociology, particularly in the Chicago school of sociology, which produced prominent ethnographies by distinguished sociologists such as William Foote Whyte (1994). However, unlike in anthropology, ethnographic fieldwork is not a requirement for a doctorate in sociology.

PROBLEMS OF EXPRESSION
Ethnography presents special challenges to the anthropologist and collaborators, and to the discipline’s status in the academy and wider society. Intimate, face-to-face research can be politically sensitive and can heighten the self-consciousness of all parties involved. The experiential and subjective nature of this mode of research opens anthropological reflections to the humanities and to ways of becoming involved in social issues. Anthropological self-questioning concerning the conditions and outcomes of knowledge production are especially acute where ethnography is concerned.

In the introduction to a controversial collection edited with George Marcus, James Clifford argued that ethnographic accounts are at best incomplete and partial truths, much like fictional works (Clifford and Marcus 1986, pp. 6–7). Clifford Geertz (1988) also interpreted anthropology as a kind of writing, a literary creation. Interest in the writing of ethnography focused attention on the rhetoric, metaphors, and tropes used by anthropologists to assert their expertise, authority, and credibility, especially when objectivist science had once held such sway in the discipline. A growing concern with narrative styles, acts of interpretation, and issues of cultural translation in ethnography began to turn the discipline in on itself, and led to the erosion of confidence in realist approaches. Expression seemed to overtake explanation as the focus of these critiques of realism that have been labeled “postmodernist.” The attention to how ethnographic texts are constructed was accompanied by an interest in the subjective and personal conditions of knowledge production, by critically examining the ways the anthropologist becomes part of and shapes the situation that is being studied. Reflexivity became a key term, prompting many anthropologists to reflect on how their personal biographies led them to certain subjects and to ways of understanding those subjects. Ethnographic filmmakers such as Jean Rouch (1917–2004) deepened and extended discussions of reflexivity, of anthropology as a humanistic art, and of ethnography as fiction, well before it became popularized as “postmodern” in the late 1980s. The question that remains open is a philosophical one: Is the mission of the ethnographer primarily to uncover truth, or to explain reality?

ETHICAL AND POLITICAL CONSIDERATIONS
The act of writing about persons is based on actual interactions, and anthropologists have been keen to elaborate ethical guidelines for fair and proper relationships with their collaborators. The basics of most anthropological guidelines stress the principles of seeking informed consent, not causing harm to individuals, leaving the field situation in the way one found it, and safeguarding confidentiality (e.g., American Anthropological Association 1998), and much wider debates have raged since the 1970s (Rynkiewich and Spradley 1976). Revelations that some anthropologists had spied for the U.S. government during counterinsurgency campaigns in the 1960s in Asia and Latin America shook the discipline. Intellectuals, media, and political leaders in recently decolonized countries, as well as indigenous peoples, charged that anthropology functioned as an imperial discipline of surveillance, and researchers became concerned with how to decolonize anthropology. New ethical guidelines have stressed the need for collaboration, coproduction, and multiple authorship, and for ongoing negotiation of the terms of access to research data. Much controversy has emerged over the status of “practicing” anthropology—anthropology done outside of the academy, in the service of governments and private firms—especially as ethical guidelines produced in the 1970s have been tempered by a concern of “practicing anthropologists” for the rights of those funding their research, such as commercial stakeholders.

Politics have been intimately tied up with issues of research, ethics, and writing. Since the 1970s more attention has been devoted to the politics of ethnography as a dominating knowledge that posits a different “other.” The rise of indigenous anthropology (Medicine 2001), feminist anthropology, and anthropology “at home” have all sought to confront and contest the colonial origins of anthropology (Biolsi and Zimmerman 1997; Brettell 1993; Deloria 1988; Harrison 1991). New approaches to ethnography call into question the older scientific “gaze” of anthropology as a kind of imperial vision that manifested itself in imperious writing—that is, writing in the “voice of god” as an unseen, authoritative, and trustwor-
thy observer. More attention has been paid to how gender, class, ethnicity, and nationality condition one’s rapport with hosts, delimit access to spheres of life, and determine what kind of data can be recorded. Reinterpreting ethnography as premised on humanistic, face-to-face, intimate relationships; delving into intersubjective understandings; and not placing oneself outside of the research context as a remote analyst or, worse, as a spectator of zoological phenomena, have worked to produce more self-conscious and politically sensitive ethnographies (Rabinow 1977). Dialogic exchanges (Crapanzano 1980) challenged the previous, sportscaster-like narrations of what people were doing.

NEW TRENDS

Self-reflection has been acute in anthropology, at times bordering on paralyzing angst. The prolonged immersion in other cultures, the everyday and intimate interactions with one’s hosts, arriving as an outsider and becoming an insider, the questions of one’s own identity and the status of one’s involvements with others almost inevitably heighten self-consciousness. Hortense Powdermaker was aware of how involvement and detachment, art and science, worked in tension with one another in ethnography (Powdermaker 1967). Currently, the relationship between theory and ethnography is tense, too, and there is a greater tendency to produce theoretically heavy accounts that seemingly render ethnographic description as secondary in importance, or as ornamentation in predetermined exercises. Debates about writing styles in anthropology were conducted largely in private, among and for other professional anthropologists, with little or no impact on the social standing and public engagement of the discipline. Some have noted the limits to discussions of reflexivity, arguing that the result has bordered on narcissism and a failure to reflect on broader-than-personal conditions of knowledge production (Bourdieu 2000). Although ethnography still addresses the impacts of postmodern and postcolonial critiques, there are new trends emerging: fieldwork in one’s home society; feminist and indigenous anthropology; autoethnography; experimental writing, including fiction in the regular sense (Bowen 1954); and militant advocate approaches. In terms of the politics of writing, there are more dialogic and multivocal texts rather than authoritative, univocal accounts. Some scholars are questioning how anthropologists conceptually constitute “the field” at the heart of their ethnographies, with increased sensitivity to the realization that there is no definite beginning and end to fieldwork, no clear “home” and “away” (Amit 2000). Revised ethnographic realism—understanding the differences between experience and reality—has led some to admit that what ethnography can capture is limited, with the resulting admission of multi-method approaches involving research in archives, media analysis, and use of statistics. Understanding how cultures are delinked from territories, with greater concern for globalization and transnational movements, has led some anthropologists to elaborate frameworks for multi-sided ethnography (Marcus 1995) premised on traveling cultures, on the movements of money, persons, metaphors, narratives, and biographies. As much as anthropology has been riven by debate about its ethnographic core, very few anthropologists have argued for abandoning ethnography. As Nancy Scheper-Hughes put it: “Not to look, not to touch, not to record can be the hostile act, an act of indifference and of turning away” (1995, p. 418).

Ethnology and Folklore

Ethnology and folklore emerged as the “science of tradition” during the nineteenth century and during the twentieth as a discipline concerned with “expressive culture” and cultural identities, particularly within modernizing societies. Professionals in these fields may call themselves folklorists or ethnologists. Whereas anthropologists frequently sought out homogeneous societies separated from the modern world, folklorists and ethnologists theorized about the persistence, adaptation, and function of tradition within complex societies.

Folklore and ethnology are related, sometimes linked, concepts for the way that individuals and groups use tradition to express values, beliefs, and ideas in a number of forms, including art, architecture, story, song, speech, and custom. Both terms refer to the process of tradition that results from informal learning: word of mouth, imitation and demonstration, and custom. The concept of folklore, however, has roots in the literary appreciation of oral and customary tradition (especially in Great Britain and America), whereas ethnology has a legacy of anthropological attention to the social and material basis of tradition, particularly in rural and peasant societies (especially in Scandinavia and Germany where holistic terms folkv and Volkskunde, respectively, circulated).

As the fields developed, however, they came together into a broad inquiry of tradition, usually spanning categories of oral, social, and material culture. Into the twenty-first century, the term ethnology is still generally used in continental Europe, broadened to include urban and emergent traditions, and folklore in Great Britain and America. Ethnology, when used in the Americas, frequently refers to the social study of native tribal groups rather than to the cultural traditions of ethnic, occupational, and other groups, as in Europe. One learned society bridging the transatlantic tendencies is the International Society for Ethnology and Folklore, based in the Netherlands.

Related terms vying for wider usage include folklife and folk culture, representing concerns for the social and material life of tradition-centered groups. In addition to The Folklore Society, Great Britain has a Society for Folklife Studies, whose journal is Folklife: Journal of Ethnological Studies. Likewise the Archive of Folk Culture in the American Folklife Center of the Library of Congress in the United States has been a national repository for field-collected materials since 1928, and national centers for “folk culture” were established in the twentieth century in India, Lithuania, Estonia, Flanders, and the Netherlands, among others. Also vying for wider usage is the term folkloristics (folkloristik in German), often implying, like its cognate of linguistics, a distinction between the material under study—language and folklore—and the scientific branch of study. Use of folkloristics often implies an analytical emphasis on structure, communication, and performance of traditional behavior.

The scholarly inquiry into tradition, often traced to the field research of German intellectuals Jacob Grimm (1785–1863) and his brother Wilhelm Grimm (1786–1859), who published a collection of folktales with comparative notes as Kinder-und Hausmärchen (Children’s and Household Tales) in 1812, signaled significant international intellectual movements that influenced the social...

18 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION

In the twentieth century, the influential American anthropologist Franz Boas (1858–1942), as editor of the Journal of American Folklore from 1908 to 1925, emphasized folklore as essential cultural evidence of an individual society. This approach signaled a shift away from global Darwinian models to a cultural relativism and historical particularism driven by a field-based ethnography of cultural distinctions and settings. Several of Boas’s students took over the editorship of Journal of American Folklore through the mid-twentieth century. The work of Boas and students such as Ruth Benedict, A. L. Kroeber, Melville Herskovits, and Martha Beckwith (who has the historical distinction of holding the first chair in folklore at Vassar College in the 1920s) in recording and interpreting texts among diverse groups including Native Americans, African Americans, and college women emphasized the idea of folklore as a reflection, or symbolic autobiography, of a culture, and the analysis of folklore’s functions within a particular society and setting.

As folklore and ethnological studies developed with a social focus, more attention was given to folk as an adjective for traditional learning that everyone participates in. Alan Dundes (1934–2005) in The Study of Folklore presented an influential definition of folk group that applied to “any group of people whatsoever who share at least one common factor” (1965, pp. 1-2). In this modern perspective, folklore, the logical, functional outcome of such a common grouping, becomes a popular, necessary expression instead of a rare find or survival. It need not even be old. As a special kind of knowledge (e.g., jokes, gestures, dress, nicknames, slang) serving the purposes of the group (expanded beyond ethnic and occupational categories to include, for example, family, deaf, gay, children’s, organizational, corporate, and Internet communities), folklore is ever changing and, indeed, can be created anew. The expressions can be analyzed functionally not only to bond the group, but also to provide psychological outlets to deal with disturbing issues and adaptive strategies to conflicts and human development. Generations of professionals with doctorates in folklore developed its study as a separate discipline with distinctive approaches. American folklorists such as Michael Owen Jones, Roger Abrahams, Dan Ben-Amos, Richard Bauman, David Hufford, and Barbara Kirshenblatt-Gimblett were instrumental in developing behavioral or performance-centered theories of folklore as “artistic communication in small groups,” while others such as Alan Dundes, Jay Mechling, Gary Alan Fine, Simon Bronner, Elliott Oring, and Henry Glassie explored the social structural and cognitive dimensions of human expressiveness.

In the twenty-first century, folklore is viewed as a dynamic process of cultural communication by which individuals discover or establish their identities. Individuals in contemporary society are understood as having multiple, often overlapping, identities that are recognized by different folkloric repertoires. Social-scientific research in folklore emphasizes field work and ethnography—the observation of “cultural scenes” in which symbolic communication and behavior occur. No longer content to collect folkloric “texts” like natural history specimens, folklorists and ethnologists interpret for the social sciences the relation of folklore to cultural “contexts.” To be sure, historical perspectives are still evident in the analysis of precedents and variations of tradition, and there is often a social-psychological consideration of the function and enactment of cultural expression in the formation of identity, both group and individual. Folklore and ethnology contribute to the social sciences by theorizing the roles of expressions in binding and differentiating groups and their identities, sustaining values and beliefs from one generation to another, and understanding the artistic components of everyday life. The folkloristic purview of groups and genres has greatly expanded since the nineteenth century, but the inquiry into tradition’s role in mind, society, and behavior remains.

ETHNOMETHODOLOGY

Ethnomethodology is an approach to the study of everyday life with a particular emphasis on the construction of cultural meanings amongst minority groups. The term incorporates the prefix *ethno-* to refer to cultural context, including language and jargon, myths, symbols, and codes of behavior, and the word *methodology*, which refers to the means, rationale, and philosophical assumptions involved in the approach to investigating such phenomena.

Developed by Harold Garfinkel in 1967, ethnomethodology was initially dismissed by prominent social theorists of the time, such as Alvin W. Gouldner (1920–1981), who described Garfinkel's work as "mere Californian sociology" (cited in Garfinkel 2002, p. 3). In spite of this early disinterest, ethnomethodology continues to influence empirical social science research in a diverse range of fields, most notably in the areas of education, health, gender, media, and criminal justice.

Specifically, ethnomethodology investigates the functioning of common sense within cultural contexts, stressing the active, reasoned, and informed character of human social behavior. Put simply, ethnomethodology is the study of how individuals maintain a sense of reality in a given social situation through the means of social interaction with other individuals. That is, a conversation is a social process of interaction that has certain requirements in order for individual participants to identify it as a conversation and keep it going as such. For example, people will look at one another, nod, murmur, take turns in speaking, and in asking and responding to questions. If these requirements are not met, or are employed in ways that deviate from the expectations attached to the perceived reality of a conversation, then the interaction breaks down to be replaced by an alternative social process.

Garfinkel's work was thus a development of the phenomenological insights of Alfred Schutz (1899–1959), who had argued that commonsense knowledge is patchy and incomplete and that shared understandings between individuals are contingent achievements based upon this revisable and approximate knowledge. Garfinkel conducted a series of quasi-experimental procedures that exposed the tacit assumptions and presuppositions that underpin shared understandings during social interaction, which he argued had to be understood as an "event-in-context." That is, linkages are assembled between a process of social interaction and the cultural context within which the interaction takes place.

Crucially, therefore, changes in the understanding of an event's context will evoke some shift or elaboration in an individual's ability to grasp the meaning and reality of the interaction itself. Put simply, to make sense of social interaction between individuals it is necessary to grasp the cultural context in which it takes place. Individuals frequently design their interaction so as to make use of localized contexts in order to elaborate and particularize the sense of their talk and actions. A useful example here is how the cultural products of the poor and minority groups, such as rap lyrics, can be misunderstood if the cultural context in which they are produced is not fully grasped.

Ethnomethodology remains a highly influential approach in the international social sciences, continuing to open up innovative areas of analysis in sociology, social psychology, and linguistics in particular.

In the 1890s aural recordings, first on cylinder records and then on discs, were made “in the field” or in recording studios such as at the Library of Congress. Early recordings supplemented written transcriptions of “exotic” music. Together with filmed musical events, aural and visual documents opened up the study of music in cultural context to a wider group of researchers. This led to a broad division in the field, between early ethnomusicologists who recorded in many different cultures in many parts of the world (Alan Lomax is a good example—see Cohen 2003) and more recent scholars who record in a few places throughout their careers and then write in depth on those few areas (Stone 2002). In keeping with a humanistic bent, which has challenged social science approaches to the field, most ethnomusicologists have become self-reflective and have subjectively inserted themselves into the musical and cultural context they study. However, whether or not ethnomusicology remains a social science, most ethnomusicologists hold a humanistic value that the music of ordinary people in their own cultural settings—as opposed to music by and for elites only—should be the focus of the discipline.

EUGENICS
Although ideas concerning the mutability of so-called natural human traits have been a part of Western civilization since antiquity, the science of eugenics emerged out of a particular nineteenth-century discourse that had its roots in social Darwinism and scientific racism. Throughout the second half of the nineteenth century, the English scientist Sir Francis Galton used statistical studies of British families to argue that heredity governed physical ability, talent, and character, and that “reputable” families were much more likely than ordinary families to produce superior offspring. He argued, moreover, that humans possessed the ability—through a system of selective breeding—to guide the course of human evolution and ultimately improve the race. In 1883, Galton named his new science eugenics, which he derived from the Greek word eugenēs, meaning “good in birth” or “noble in heredity.”

Following the publication of his famous cousin Charles Darwin’s On the Origin of Species in 1859, Sir Francis Galton began his inquiry into human heredity and the use of science to improve the human race. His first attempt to articulate his thoughts concerning the power of nature in determining human ability came in the form of a two-part article entitled “Hereditary Talent and Character,” which was published in a popular English magazine in 1865. In another article entitled, “Hereditary Improvement,” published in 1873, Galton established his method for improving the quality of the human race. He declared that his goal was to “improve the race of man by a system which shall be perfectly in accordance with the moral sense of the present time” (Gillham 2001, pp. 195–197). To implement his plan, Galton envisioned the creation of a state agency that would gather, analyze, and distribute important pedigree data, accompanied by photographs and physical measurements, to all Englishmen interested in improving the race. This information would then be used to encourage the reproduction of those families perceived to have talent, and to discourage the reproduction of the masses of individuals perceived to be of inferior quality. Programs designed to encourage “fit” individuals to reproduce came to be known as positive or productive eugenics, and those programs designed to prohibit “unfit” individuals from reproducing came to be known as negative or selectionist eugenics.

By the beginning of the twentieth century, eugenics had become very popular among a broad array of Americans eager to remedy the social, cultural, and political upheaval caused by decades of massive industrialization, urbanization, and immigration. Men such as Charles B. Davenport and Harry Laughlin of the Eugenics Record Office at Cold Spring Harbor, New York, embraced the new science. Women reformers such as Margaret Sanger also extolled the benefits of controlled breeding. In the 1920s, eugenicists created the American Eugenics Society, and the Eugenics Research Association. American eugenicists played a critical role in the passage of a 1924 immigration law known as the National Origins Act (or the Johnson-Reed Act), which greatly reduced the number of southern and eastern Europeans entering the United States. Harry Laughlin and other eugenicists wrote the Virginia sterilization law that became the focus of a 1927 Supreme Court decision in Buck v. Bell. The court voted to uphold forced sterilization, ultimately resulting in the sterilization of over 65,000 individuals throughout the United States. Eugenic ideology also made possible studies such as the controversial Tuskegee syphilis study, which focused on African American males and lasted forty years, from 1932 to 1972.

Eugenics was not limited to England and the United States. Societies across the globe embraced the new scientific thinking. In Germany, Alfred Ploetz and other scientists applied American eugenics to the new science of race hygiene, resulting in the creation of the Society for Racial Hygiene and the eventual Nazi extermination of millions of Jews, Gypsies, persons with disabilities, and other “unfit” individuals during World War II. Throughout the twentieth century, Scandinavian countries coerced large populations, consisting mostly of women welfare recipients, to be sterilized in an effort to reduce the number of genetic “flaws” among their offspring. In places such as Argentina, Brazil, and Mexico, eugenics greatly influenced biological and cultural definitions of race and gender, as well as popular notions of national “fitness.” In Latin America, the state regulated reproduction through different legal restrictions imposed on marriage.

Eugenic thought has loomed large in the public discourse and social policy of numerous countries throughout the world since the late nineteenth century. It has assumed many forms; it has spanned the geopolitical spectrum; and although it fell into disfavor after World War II, it has experienced a resurgence in the late-twentieth and early twenty-first centuries. The advent of the Human Genome Project and other advances in genetic science has ushered in new concerns about the moral, ethical, and racial implications of selective breeding. In his recent best-selling book Freakonomics, the University of Chicago economist Steven D. Levitt caused a tremendous stir when he argued that abortion has been the most dominant factor in declining crime rates in the United States. Put simply, Levitt argued that unwanted children are
more likely to become criminals, and that since the 1973 
Roe v. Wade decision fewer unwanted children have been 
born, resulting in a reduction in American crime rates. 
Critics have since charged Levitt with being a eugenicist 
who advocates the selective extermination of “at-risk” off-
spring. Although this was not his intent, Levitt has sub-
sequently been forced to defend his abortion hypothesis in 
a number of popular media outlets. Clearly, and under-
standably, anything that even remotely smacks of eugenics 
continues to create a firestorm of controversy.

EURO, THE

The euro regime is an epochal economic paradigm of 
supranational macroeconomics, based on a common con-
tinental economy with a common currency. On January 
1, 1999, eleven of the original fifteen European Union 
(EU) members (Austria, Belgium, Finland, France, 
Germany, Ireland, Italy, Luxembourg, Netherlands, 
Portugal, and Spain) elected to voluntarily surrender their 
monetary sovereignty and adopt the euro as a common 
currency, which would be managed by a common central 
bank, The European Central Bank (ECB). Greece joined 
the following year. This group of nations, known as the 
EU12, became the euro regime. Denmark, Sweden, and 
the United Kingdom have thus far not adopted the euro 
and each continue to use its own currency. Ten new mem-
bers were admitted to EU membership in May 2004, and 
they will join the euro regime when they meet the guide-
lines of the Maastricht Treaty adopted by the ECB.

The euro began as an accounting unit and came to be a 
medium of exchange on January 1, 2002. For another 
twelve months, each member economy was allowed to 
have joint circulation of their national currency along 
with the euro. Thereafter, the euro became the exclusive 
medium of exchange of the euro regime. The new cur-
rency soon became the store of value not only for the euro 
regime, but also for the rest of the world. Holding a part 
of the GDP (gross domestic product) of an economic unit 
in money, the most liquid form of asset, is a familiar prac-
tice. Because the nation-state economies of the world at 
the present time hold their international reserves in dollar 
and euro, each of the two currencies represents over-
whelming shares of world output and trade. The compet-
itive shares of official holdings of euros and dollars merit 
attention. In 1999, the dollar had a 71 percent share of 
official world holdings of foreign exchange, while the euro 
began with a nearly 18 percent share. By 2004, reserve val-
ues of dollars and euros had been climbing steadily. 
However, the world share of dollar holdings had fallen by 
6.5 percent by 2004, while that of euro shot up by more 
than 39 percent.

On January 1, 1999, the euro was launched at a 17 
percent premium over the dollar, based on the market 
quotation of the day. Within a year, the euro depreciated 
to converge with the dollar, and it continued to fluctuate 
below the value of the dollar until 2002. A psychological 
attachment to national currencies, as well as their joint 
circulation with the euro, prevented a significant strength-
ening of the euro. Soon after the euro became the exclu-
sive medium of exchange of the EU12, it appreciated over 
the dollar. International uncertainty and terrorism, as well 
as the mounting national debt and budget and trade 
deficits of the United States, compromised the competi-
tive value of the dollar vis-à-vis the euro. In addition, fluc-
tuations in the price of both petroleum and gold in the 
world market (based on and quoted in dollars) have had 
an impact on the relative strength of the euro. Meanwhile, 
successive interest rate increases by the U.S. Federal 
Reserve Bank beginning in 2004 contributed to an 
increasing demand for the dollar. The ECB responded by 
raising its core interest rate at the end of 2005. In 
December 2004, the dollar reached a record low against 
the euro, falling some 36 percent from its high against the 

As the EU share of world output and trade has 
become competitively large, the euro has progressively 
become a global currency. In 2004, the gross domestic 
product of the EU12 stood at US$8.2 trillion, compared 
with US$11.0 trillion in the United States (OECD 2005). 
In shares of world trade (exports and imports), the euro 
regime leads the United States by substantive margins. 
The comparative strength of a currency must relate 
directly to its shares of world output and trade. Given this 
criteria, the euro will continue to be a dominant currency. 
It has been suggested that Denmark, Sweden, and Great 
Britain will eventually join the euro regime, as will the ten 
new members of the EU. Then these twenty-five members 
of the EU (the EU25) will have more competitive shares 
of world output and trade than the EU12 now has, which
will have a significant impact on the euro-dollar exchange rate. In the 1960s, the U.S. dollar, based on a fixed gold value, was king, and its acceptance was global, at least within the free-market economies. Today, the euro and the dollar are the only two competitive global currencies.

The concept of geo-economics has replaced the cold-war concept of geopolitics. Based on the principle of competition, the euro and dollar currency regimes will contribute to the global optimization of economic gains for all micro units (households as units of consumption and businesses as units for investment). The European Union will be a learning model for other continents, and the Asian Economic Community, the African Economic Union, the American Hemispheric Economic Union, and the Free Trade Area of the Americas (FTAA) will increasingly command attention (Dutta 2005, 2007). The African Union has been formally instituted and others are in advanced preparatory stages.

To fully appreciate the role of the euro, one must have a comprehensive understanding of Jean Monnet’s vision of Europe as one common European family (1978). An integrated economy in a continental geographic unit, with well-specified intraregional micro- and macroeconomic parameters, both transparent and judicially enforceable, is now in place. The Free Trade Area of the EU, with one common membership and one vote in the World Trade Organization (WTO), is unique. The euro is common currency for the euro regime, and it will therefore eventually lead to one Europe, to one political union (Issing 1996; Vanthoor 2002).

EUROPEAN UNION

The European Union (EU) is a cooperative entity that has qualities of both a federal nation-state and an international organization. It is neither, but falls somewhere in between. The EU is comprised of twenty-five member-states with around 460 million citizens. All member-states are democratic countries, which have agreed to cede some of their sovereignty to the institutions of the EU by participating in the common market, making their domestic laws conform to EU laws, adopting the Euro as a common currency, and allowing free movement of goods, capital, and persons, among other things. Social scientists attempt to explain why the EU came about, the role of its institutions in promoting cooperation, and its future trajectory. Will it continue to become more federal or will it reach policy gridlock? Will it continue to enlarge or will it reach its absorption capacity?

FORMATION OF THE EU

The earliest precursor to the EU was the European Coal and Steel Community (ECSC), formed in the wake of World War II as European countries sought a way to prevent such destruction from happening again. They believed if they became economically interdependent, they would be less likely to repeat the mistakes of the past. In addition, ECSC would make economic recovery and industrial modernization possible. For West Germany in particular, Chancellor Konrad Adenauer saw it as an opportunity for rapprochement with France and new ties with the West.

It was the 1950 Schuman Declaration that unveiled Jean Monnet’s idea of the ECSC. Six member-states (Italy, France, Belgium, Luxembourg, The Netherlands, and West Germany) signed it into being with the 1951 Treaty of Paris. The ECSC was so successful in the early 1950s that it led to the 1957 Treaties of Rome, establishing the European Economic Community (EEC), which was a customs union, and the European Atomic Energy Community (Euratom). The 1967 Merger Treaty merged the executive bodies of the three treaties, thereby creating
the institutions that continue to exist in the twenty-first century. In addition, ECSC, EEC (later EC), and Euratom became known together as the European Communities. The 1987 Single European Act replaced the Treaty of Paris and the Treaties of Rome as the EC’s policy domain grew into new areas not encompassed by the original treaties. It remained the European Communities until member-states signed and ratified the 1992 Maastricht Treaty, officially creating the European Union, which established the economic, monetary, and political union.

The basic evolution of these treaties embodies not only structural and institutional changes, but an increasing recognition of Europeans’ common values, goals, and even identity, as well as a willingness to vest more authority in EU institutions. Besides economic integration—the largest area of common jurisdiction—there are common policies on agriculture, culture, energy, the environment, transportation, crime, and defense, among other things. Moreover, the EU has become increasingly political over time. In addition to increasing areas of jurisdiction, the EU has experienced successive enlargements, and the treaties have also attempted to accommodate its growing size. Membership in the EU has been so attractive that many European countries have voluntarily undergone extensive measures to democratize and develop economically so that they meet the criteria to begin accession negotiations.

EU INSTITUTIONS

At the core of the EU are its institutions, which are located in Brussels, Strasbourg, and Luxembourg. The European Parliament is the only representative institution as its members are directly elected, and belong to European political parties of which there are seven. It shares some decision-making authority with the Council of the European Union, which is an intergovernmental institution comprised of ministers and ambassadors from the member-states. The Council presidency, which sets the agenda for the EU, rotates every six months. Through the co-decision procedure, the Parliament and Council together take policy decisions, pass laws, and approve the EU’s €100 billion annual budget. However, it is only the European Commission that can initiate new laws. The Commission, unlike the Council, represents EU interests as a whole, rather than the interests of individual member-states. Commissioners are required to swear an oath of loyalty to this effect. There is one Commissioner from every member-state, chosen by their national governments, and only the European Parliament has the ability to approve the College of Commissioners or dissolve it. Still, the parliament is rather weak compared to the Council and Commission, and this is problematic given that it is the only directly elected body.

Besides these three major EU institutions, the European Court of Justice (ECJ) has played a significant role in the operations of the EU, and in pushing integration forward. The ECJ is comprised of one judge from each member-state, and its primary role is to ensure that national law is compatible with EU law. In their 1993 article “Europe before the Court: A Political Theory of Legal Integration” Anne-Marie Burley and Walter Mattli argue that the judicial legitimacy of the ECJ has enabled it to take on more jurisdiction than had been intended, and to create precedents that assert the primacy of EU law over domestic law. Consequently, many individuals and local judges bring cases directly to the ECJ instead of to their national courts. Other important institutions are the European Central Bank, Court of Auditors, the European Economic and Social Committee, and the Committee of the Regions.

HOW IT WORKS

Besides the business of initiating and approving new laws, the EU has undergone major changes to its treaties. Member-states have willingly ceded increasing levels of sovereignty in numerous policy areas, but their control of the treaties is fundamentally intergovernmental. In order to change the jurisdiction of the EU fundamentally, statesmen must negotiate a new treaty at an Intergovernmental Conference (IGC). However, as argued in Mai’a K. Davis Cross’s The European Diplomatic Corps (2007), the process of negotiation is much more complex than just the IGC summit, which is typically a highly publicized two-day event. Personal representatives of the statesmen, who are usually ambassadors based in Brussels, take years to prepare a draft treaty in advance of the IGC. Ultimately, agreement must be unanimous, and member-states can choose their own method of ratification, either through a parliamentary vote or popular referendum.

The last extensive revision to the EU was the 1992 Maastricht Treaty, which created the so-called “pillar system.” All of the policy areas that used to fall under the EC became the first pillar, which is governed by the “community method.” That is, in these policy areas the EU has full control at the supranational level, above the level of national governments. The second two pillars are intergovernmental, with the Common Foreign and Security Policy as the second pillar, and Justice and Home Affairs as the third.

A major part of the first pillar is the Single Market, which removed trade barriers among member-states, as well as establishing free movement of goods and a common tariff for imports from outside of the EU. The Single Market was part of the Treaty of Rome, but it was not fully completed until 1993. The Maastricht Treaty introduced the single currency, the Euro, which went into circulation...
on January 1, 2002. The benefits of a single currency are that it makes economic transactions easier, encourages investment, and completely eliminates exchange rate fluctuations. All member-states, including the ten new ones, have adopted the Euro, with the exception of the United Kingdom, Denmark, and Sweden. The European Central Bank, established in 1993, is completely independent of member-states and interests groups, and is charged with managing the Euro and Single Market, setting the EU's external exchange rate policy, and ensuring price stability and low inflation within the EU.

In addition to free movement of goods, the Maastricht Treaty also established free movement of persons, capital, and services, although certain restrictions still apply. Free labor mobility is of particular importance as it clearly distinguishes the EU from other free trade areas like the North American Free Trade Agreement (NAFTA). Europeans actually have citizenship in the EU, and can move, study, travel, and work within an internally borderless EU.

The Treaty Establishing a Constitution for Europe—negotiated between June and October 2004 and signed by all EU governments on October 29—was an attempt to revise the EU Treaty. But the ongoing national ratification process resulted in failure when the French and Dutch referenda in May and June 2005 rejected it. Nevertheless, the ratification process continued in 2006 even as efforts were underway to devise a new version.

THE FUTURE OF THE EU
There are numerous scholarly debates over why the EU has continued to deepen its policies, and what its future holds. Functionalist have argued that the process of EU integration has proceeded based on functional need, and on an ad-hoc basis. Neo-functionalist have argued that once the six member-states founded the ECSC a spillover effect ensued, in which one policy area necessitated integration in other, related policy areas. For example, economic cooperation spilled over into political cooperation.

Since the 1990s the major debate has typically been between rationalists and constructivists. Rationalists argue that integration proceeded based on cost-benefit calculations. At each juncture, leaders only agreed to more integration if it directly benefited their own states’ economic and power interests. Rationalists deny that any significant political integration can ever take place. On the other hand, the constructivist approach argues that the EU is a product of shared norms, which grow over time through deliberation, persuasion, and socialization. There is a certain idea of Europe that many Europeans believe is a worthwhile goal, and they comply with EU rules because they know it is in the long-term benefit of everyone. Depending on the approach, predictions about the future of the EU vary.

The question of how far enlargement can continue is also an area of attention. With the addition of ten new member-states in 2004, many scholars and politicians argue that the EU has reached its absorption capacity in the near term, and will have to wait many years before it is ready to undergo further enlargement. If the EU enlarges too quickly, it may be impossible for Europeans to continue to deepen integration, or deal with problems of democratic accountability at the supranational level.

Finally, scholars and policy practitioners debate the future role of the EU as an international actor. The strength and cohesion of the EU internally has a direct impact on its relations with the United States, its growing global security role, and its ability to be economically competitive. The EU has played a strong role in facilitating the ongoing Middle East peace process. Its policy is to favor the creation of two states to resolve the Israel-Palestinian conflict, and to find a solution to the Palestinian refugee crisis. The EU participates in numerous diplomatic and humanitarian assistance efforts to ensure the success of the roadmap to peace. The EU is the largest trading, scientific, and research partner with Israel, and provides the greatest amount of aid to the Palestinians and United Nations Relief and Works Agency. The EU responded to the 2006 crisis in Lebanon with numerous high-level diplomatic meetings with both Lebanese and Israeli governments, the international community, and the United States. It also devised evacuation and humanitarian corridors to assist victims in escaping the violence, or to get supplies into the region.

Besides extensive aid to the Middle East, EU member-states as a whole give about $30 billion per year in development cooperation or aid to the third world more generally. Recipient countries include seventy-seven African, Caribbean, and Pacific countries. The EU seeks to reduce poverty in the third world by slowing the spread of HIV/AIDS, increasing education, providing debt relief, and improving the coherence between development and trade policies. To that end, the EU supports a number of associated territories, giving them preferential treatment and access to the European Development Fund for financing projects.

Overall, the EU leads the world in environmental protection and humanitarian aid, its economy is roughly the same size as that of the United States, and it has a high level of soft power or influence. While there are many areas of controversy and hurdles to cooperation in the foreseeable future, the EU has repeatedly proven itself to be a viable world player with much potential.

**EUTHANASIA AND ASSISTED SUICIDE**

The twentieth century has seen great strides in the advancement of medicine and life-sustaining technology, resulting in improved life expectancy and quality of life for people around the world. Improvements in medicine, however, raise questions about the appropriateness of life-sustaining treatments in the case of people who are terminally ill and experiencing acute pain and suffering. In the late twentieth century, end-of-life issues came to the forefront of public attention, resulting in an ongoing discussion about ethical, legal, and political implications of physician-assisted suicide (PAS) and euthanasia.

**ISSUES SURROUNDING CONTROVERSIAL END-OF-LIFE DECISIONS**

Part of the controversy surrounding end-of-life decisions such as PAS and euthanasia results from a lack of clear communication as to what these actions entail. *Euthanasia* refers to someone (often a physician) intentionally taking an action that ends another person's life with the stated intent of alleviating or preventing perceived suffering. *Euthanasia* involves the direct administration of lethal medication by a person other than the terminally ill patient. “Assisted suicide is the deliberate and knowing provisions of information, the means, and/or help to another person for the act of suicide” (American Association of Suicidology 1996, p. 6). In PAS, the assistant is a medical doctor. Such assistance is typically in the form of a prescription for a lethal dose of medication that the terminally ill patient may use as a means to end his or her life. The critical distinction between these practices is that in euthanasia the physician (or somebody else) actively administers the lethal medication, while in PAS the patient is given the means to bring about his or her own death.

There are various types of euthanasia, including voluntary, nonvoluntary, and involuntary. *Voluntary euthanasia* refers to deliberate termination of a patient's life upon that person's explicit and direct request. Nonvoluntary euthanasia occurs when the patient is unconscious or incompetent and is thus unable to make a decision. Involuntary euthanasia takes place when the patient is competent and aware but his or her consent is not obtained. It should be noted that involuntary euthanasia is not an acceptable practice even in countries where voluntary euthanasia is currently legalized. The involuntary termination of a patient's life is not supported by legislation and is considered homicide around the world. This distinction has led several authors to argue that euthanasia is by definition voluntary and that terms such as nonvoluntary and involuntary euthanasia are contradictory and misleading (Materstvedt Clark, Ellershaw, et al., 2003).

In addition, distinction has been made between active and passive euthanasia. *Active euthanasia* is the procedure whereby a physician (or someone else) shortens a person's life, usually through the administration of a lethal dose of medication. *Passive euthanasia* refers to the practice of withholding or withdrawing a futile or ineffective treatment upon the patient's request (American Association of Suicidology 1996). Several researchers have argued against the use of this latter term by pointing out that practices such as withholding and withdrawing treatment are ethically and legally distinct from active euthanasia (Materstvedt, Clark, Ellershaw, et al. 2003). This view is consistent with practices in countries such as the United States and Israel where euthanasia is illegal, but withholding and withdrawing treatment are acceptable medical practices (Ganz, Benbenishty, Hersch, et al. 2006). However, in other countries the term passive euthanasia is still used. Similarly, providing high doses of pain-relieving medication, even if this may shorten a patient's life, is seen as distinct from euthanasia (Materstvedt, Clark, Ellershaw, et al. 2003). This is also the case with terminal sedation, a practice whereby pain medication is used to bring about unconsciousness, after which life-support equipment is withdrawn (Parpa, Mystajudou, Tsilika, et al. 2006).

**ARGUMENTS REGARDING PAS AND EUTHANASIA**

A firm grasp on the definitions of PAS and euthanasia as well as on the alternatives that exist to these practices is essential for an informed understanding of the debate sur-
rounding end-of-life decision-making. As of the early twenty-first century, more empirical data are necessary in order to evaluate the accuracy of arguments in favor of and against PAS and euthanasia.

Proponents of assisted suicide and euthanasia claim the practices exist but are hidden, and legalizing such acts would allow for stricter government regulation and control (Quill and Battin 2004). In addition, involving medical practitioners in the decision-making process would allow for professional and expert judgment to be made regarding the validity of end-of-life decisions. Another fundamental argument in favor of legalizing PAS and euthanasia is maximizing personal autonomy and self-determination. According to this view, a terminally ill patient who is enduring unbearable pain or suffering is entitled to the right of choosing death with dignity and peace. Alleviation of unnecessary suffering and maintaining the quality of life of terminally ill patients are the paramount goals behind PAS and euthanasia. Some proponents of PAS claim that this practice is ethically different from euthanasia, as in PAS the patient is the one who performs the act of ending his or her life. Opponents of euthanasia and PAS point out the potential for abuse if these practices are granted legal recognition (Foley and Hendin 2002). Critics of PAS and euthanasia often refer to the threat of a slippery slope. They fear that once voluntary euthanasia or PAS for terminally ill patients becomes legally permissible, other forms of medicalized killing, such as involuntary euthanasia for mentally incompetent and/or disabled individuals would increase. Many medical professionals state that euthanasia and PAS are prohibited under the Hippocratic Oath and violate the fundamental ethical principles of nonmaleficence and beneficence. Furthermore, these professionals argue that the need for such end-of-life decisions can be eliminated with the provision of appropriate palliative care and the effective use of pain control medication.

Questions have also been raised about the stability and rationality of end-of-life requests (Foley and Hendin, 2002). In addition, patients may request PAS or euthanasia as a result of experiencing hopelessness and depression rather than acute physical pain or suffering. Alternatively, the patients may feel obligated to alleviate their families from unnecessary burden and thus feel pressured to end their lives. Finally, many opponents claim that the sanctity of human life overrules concerns of personal autonomy and that the protection of human life should be of paramount importance in end-of-life medical cares.

INTERNATIONAL VIEWS OF PAS AND EUTHANASIA

Both euthanasia and PAS were legalized in the Netherlands in 2002 after they had been tolerated for more than 30 years (Materstvedt, Clark, Ellershaw, et al. 2003). Belgium legalized euthanasia in September 2002, and did not legalize PAS (Adams and Nys 2003). Physician-assisted suicide, but not euthanasia, was legalized in Oregon in 1994 with the Death with Dignity Act, and began to be in use in 1997 (Materstvedt, Clark, Ellershaw, et al. 2003). In 2006, the Oregon Department of Human Services announced that it will no longer use the term “physician-assisted suicide” to describe deaths under the Death with Dignity Act (Colburn 2006) because the act itself specifies, that deaths that occur following the provisions of the law are not to be considered suicide. Although active euthanasia is illegal in Switzerland, assisting in the suicide of a terminally ill patient is considered a crime only if the death, and therefore the motive behind the assistance, benefits the person who assists the suicide (Schildmann, Herrmann, Burchardi, et al. 2006). Although Australia’s Northern Territory was the first jurisdiction to legalize euthanasia in 1995, the Rights of the Terminally Ill Act was repealed nine months later by an act of the Commonwealth (Materstvedt, Clark, Ellershaw, et al. 2003).

The legalization of PAS and euthanasia in several nations signals changes in public awareness of end-of-life issues. However, countries with legal endorsement of these interventions are the exception rather than the rule. A 2001 survey conducted by the Council of Europe (2003) revealed that a majority of European nations do not have laws concerning assisted suicide and euthanasia. Of those nations that do have laws, the overwhelming majority oppose the practices. A 1999 study by Luigi Grassi, Katia Magnani, and Mauro Ercolani, published in the Journal of Pain & Symptom Management, found that only 15 percent of Italian physicians favored euthanasia and assisted suicide. In Ireland, where suicide was considered a crime until 1993, discussions of euthanasia and assisted suicide have been taboo (Phillips 1997).

Euthanasia is not a legal option in Germany and physicians are obligated to prevent harm, which may also include cases of attempted suicide. However, suicide and assisted suicide are not considered criminal acts because of an artifact of German law (Schildmann, Herrmann, Burchardi, et al. 2006). This creates a precarious situation in which assisted suicide is theoretically an option for German physicians but may lead to legal sanctions if an argument is made that there was a duty to protect the patient’s life. As of 2003, open discussion on PAS and euthanasia does not exist in Bosnia-Herzegovina (Haračić 2003), and Estonia has not engaged in a public debate surrounding end-of-life issues (Koorits 2003). In Greece, only 8.1 percent of the general public and 2.1 percent of physicians favor PAS, although 56.7 percent of the surveyed medical doctors had administered terminal sedation (Parpa, Mystajudou, Tsilika, et al. 2006). In Russia,
Euthanasia and Assisted Suicide

euthanasia is seen as contrary to the physician’s duty to preserve and promote human life and is therefore considered unethical and illegal (Leenaars and Connolly 2001). In contrast, a large percentage of physicians in China may approve of euthanasia, although such acts are not officially legalized (Leenaars and Connolly 2001). In India, 50 percent of medical students favor euthanasia (Leenaars and Connolly 2001). Israeli medical doctors view euthanasia, PAS, and withdrawing of treatment as being forbidden by Jewish ethics and law; however, withholding of treatment is an accepted practice (Ganz, Benbenishty, Hersch, et al. 2006).

Issues of culture, religion, and national history are critical when attempting to explain the observed differences in beliefs about end-of-life decision-making. Several authors have hypothesized that positive attitudes toward PAS and euthanasia are the product of highly industrialized, individualistic societies (Kemmelmeier, Wieczorkowska, Erb, and Burnstein 2002). For example, an increase in positive attitudes regarding autonomy in the United States beginning in the late twentieth century has been correlated with a shift toward more positive attitudes regarding assisted suicide (Kemmelmeier, Wieczorkowska, Erb, and Burnstein 2002). In collectivistic societies such as Japan, arguments about the right to self-determination hold less appeal and end-of-life decisions are seen as prerogatives of the family as well as of the individual patient (Konishi and Davis 2001).

This picture is complicated by differences in religion. Most religions of the world uphold the sanctity of human life and prohibit actions that intentionally hasten death. Catholicism officially disapproves of euthanasia and PAS, as does the Christian Eastern Orthodox Church (Parpa, Mystajudou, Tsilika, et al. 2006). There are a variety of branches of Judaism, some of which oppose the active shortening of human life but deem interventions that artificially extend the agony of terminally ill patients unnecessary, therefore allowing withholding and withdrawing treatment (Gesundheit, Steinberg, Glick, et al. 2006). Islam does not recognize a patient’s right to die but allows for non-treatment decisions such as withholding and withdrawal of treatment to be made by the patient’s family and community (Sachedina 2005). Islamic law also condones the use of pain-reducing medication at the risk of shortening the life of a terminally ill patient (Sachedina 2005).

Views about euthanasia and PAS are further affected by national history. The term *euthanasia*, for example, evokes negative memories in many German-speaking countries where the term was used during the Nazi regime to refer to the systematic extermination of six million Jews and more than 200,000 mentally ill and physically disadvantaged people, as well as the Roma (Schildmann, Herrmann, Burchardi, et al. 2006) and other groups. Such historical experiences have prohibited public discussions of euthanasia in Germany (Schildmann, Herrmann, Burchardi, et al. 2006).

CONCLUSION

Given the advances in life-sustaining technology and medical treatments, the controversy surrounding end-of-life decision-making is likely to continue, at least in technologically advanced countries. Open discussion of PAS and euthanasia is complicated by a constantly evolving terminology and differing cultural, religious, and national ideals. People need to stay informed of current developments and research on these issues in order to be prepared to face the end-of-life dilemmas of the future.

E. E. Evans-Pritchard was one of the world’s leading social anthropologists from the 1940s to the 1960s, his work marking a transition from structural-functionalism to cultural interpretation and history. His theoretical statements on the aims of anthropology and his ethnographic writings on African societies were equally influential.

As an undergraduate, Evans-Pritchard studied history at Oxford University. For his postgraduate studies in anthropology, he moved to the London School of Economics (LSE) to work with the English ethnologist Charles G. Seligman (1873–1940). Another strong influence on Evans-Pritchard during his LSE years was the British anthropologist Bronislaw Malinowski, despite an intense mutual dislike between them. Evans-Pritchard received his Ph.D. in 1927 for a thesis on the Azande. Along with Raymond Firth, Isaac Schapera, Audrey Richards, Siegfried Frederick Nadel, and others, Evans-Pritchard was part of a group of students trained by Malinowski who came to occupy key positions in social anthropology from the mid-1940s to the 1970s. Evans-Pritchard did extensive ethnographic fieldwork among several African societies, most notably among the Azande and Nuer (both in the southern Sudan). He stayed in Africa during World War II to fight for Britain against Italian troops. He converted to Roman Catholicism in 1944, and his religiosity subtly colored his writings on belief systems. After World War II, Evans-Pritchard settled down as professor at Oxford University (1946–1970) where he attracted a large number of students from around the world. He was president of the Royal Anthropological Institute (1949–1951), co-founder of the Association of Social Anthropologists (ASA), and was knighted in 1971.

Evans-Pritchard was a prolific writer, with more than 400 publications to his credit. In *Witchcraft, Oracles and Magic among the Azande* (1937), he developed an ethnographic perspective on apparently irrational modes of thought. This work on the internal coherence of witchcraft beliefs fascinated philosophers such as Robin George Collingwood and Michael Polanyi, and remains one of anthropology’s most acclaimed monographs. In *The Nuer* (1940), the first of several books on this cattle-farming society, Evans-Pritchard pioneered an approach to social ecology. His analysis of how the Nuer derive their modes of time-reckoning from kinship relations and economic activities is a classic reading in the anthropology of time. The edited volume *African Political Systems* (1940) develops a comparative perspective on African political traditions, with a view to facilitating British colonial governance. Evans-Pritchard often acknowledged Alfred Reginald Radcliffe-Brown as his main inspiration, but his BBC lectures on *Social Anthropology* (1951) make a noticeable shift from structural-functionalism to ethnohistorical interpretation. Placing anthropology among the humanities, he argued that “social anthropology is best regarded as an art and not as a natural science” (1951, p. 84) and that the “translation” of cultural concepts is at the core of the discipline. A fruitful combination of anthropology and history informs many of his works. In *The Sanusi of Cyrenaica* (1949), he retraced the history of this North African Sufi order from 1837 to 1942 and provided a grim assessment of Italian colonialism in the region. Later works, such as *The Azande: History and Political Institutions* (1971), further confirm his rejection of synchronic perspectives (typical of both structural-functionalism and structuralism) toward interpreting historical change.
Event Studies

Evans-Pritchard’s early works were always widely acclaimed. His later turn to history and interpretation initially received hostile reactions, but laid the groundwork for many developments in anthropology since the 1980s. In the early twenty-first century Evans-Pritchard’s status as a classic of social anthropology is undisputed.

EVENT STUDIES

In the social sciences, there are instances where it is necessary to statistically assess the impact of an event on the value of the firm. In this instance, event studies are a viable tool to quantitatively assess the effectiveness of an “announced event” on the stock returns of firms. The announced event is an unanticipated event, which may have political, economic, legal, or historical implications for select firms. The stock returns of the firm are often referred to as shareholder wealth or the welfare of the firm; and assuming efficient markets, the market reaction to an announced event will be immediately reflected in the security prices (or share returns) of the firm.

DESCRIPTION OF AN EVENT STUDY

To construct an event study, a specific event and the date of the announced event, called the event date, must be identified. The event date may be found in prominent media outlets such as the New York Times, Wall Street Journal, the Associated Press, or other media outlets. Thereafter, the event window must be constructed, which is typically the event date. The event window may be extended to include the day before and the day after the actual announcement, as some announcements may occur when the stock market has closed and/or the information was leaked the day before. Alternatively, an anticipatory window may be constructed that includes days before the actual announcement to account for potential leakages prior to the actual announcement.

After the event window is constructed, the stock returns of the firm must be collected to construct an estimation window, which represents the stock returns under “normal” conditions (no confounding events have occurred such as annual report announcements, restructuring announcements, etc.). The estimation window is typically before the event window, and therefore does not include days in the event window to avoid influencing the estimation of returns under normal conditions. A selection criterion must also be determined for the inclusion of firms in the event study such as industry membership and/or data availability. Further, any potential biases during the firm selection must be disclosed.

To determine the market reaction to a specific event, the abnormal returns are constructed, which determines, on average, if the firm observed above or below average returns in response to an announced event. Specifically, assuming efficient markets, abnormal returns represent the market’s valuation of the change in the firm’s current and future expected profitability due to an announced event.

APPLICATIONS OF EVENT STUDIES

IN THE SOCIAL SCIENCES

There have been many applications of event studies in the social sciences. Event studies have been used to determine the impact of presidential elections on the stock market. Srinivas Nippiani and Bobby Medlin examined the impact of the delay in the declaration of a winner in the 2000 U.S. presidential election on the performance of the stock market and found a negative reaction to the delay in election results. Nippiani and Augustine Arize also found evidence that the delay in the U.S. election results impacted the stock markets in other countries like Mexico and Canada. Sara Ellison and Wallace Mullin analyzed President Bill Clinton’s 1990s health care reform proposal on pharmaceutical stock prices and found that investors reacted negatively to health care reform, estimating that shareholder wealth fell by approximately 52 percent.

Event studies are also used to determine the impact of trade policy announcements on the value of the firm. John Hughes, Stefanie Lenway, and Judy Rayburn exam-
ined the stock price reactions for the semiconductor producers and downstream consumers (electronic and computer firms) affected by a subset of events starting with the filing of a Section 301 petition by the U.S. semiconductor industry alleging unfair practices by the Japanese and culminating in the 1986 Trade Agreement. Empirical evidence suggests that U.S. semiconductor producers and consumers benefited from the trade agreement. In previous trade studies, statistical results have shown that U.S. firms observed positive abnormal returns in response to the announcement of U.S. trade protection. Bruce Blonigen, Wesley Wilson, and Kasaundra Tomlin note that the studies of trade policy on the welfare of the firm ignore the possibility that foreign firms can use foreign direct investment to mitigate the positive gains to domestic producers, also known as “tariff-jumping.” Using event study methodology, the statistical results suggest that affirmative U.S. antidumping decisions yield positive abnormal returns; moreover tariff-jumping in the form of new plants or plant expansions by foreign firms has a negative impact on the welfare of U.S. domestic firms that previously received trade protection.

Issues related to human resources and human rights have also been evaluated using event study methodology. Michelle Arthur and Alison Cook examined the share price reactions to 231 work-family human resource policies adopted by Fortune 500 companies, which were announced in the Wall Street Journal from 1971 to 1996. The results suggest that firm announcements of work-family initiatives positively affected the shareholder wealth of firms that implemented them. With respect to human rights issues, Judith Posnikoff analyzed the effects of announcing divestment or withdrawal of U.S. firms from South Africa during the 1980s on those firms’ shareholder wealth and found a significant positive announcement effect.

STRENGTHS AND LIMITATIONS
Event studies are a valuable tool, in that across many disciplines in the social sciences one can assess the effects of new information on the shareholder wealth of specific firms; and in some cases perform industry-level analysis. There are some limitations in the methodology. For example, it is difficult to identify the exact date of a specific event. In addition, there are some estimation issues, which Craig MacKinlay discussed in a 1997 survey article on event studies that outlines the issues and remedies. In sum, assuming efficient markets, event study methodology is a valuable statistical tool to evaluate issues in the social sciences.

EVOLUTIONARY GAMES
The modeling of evolutionary games has established itself as an important theoretical tool in the social sciences. Evolutionary games have proven useful in deriving descriptively accurate models of human behavior in an economic context, and they have provided important insights regarding the origins of conventions and other social behavior. Indeed, it is a testament to the power of evolutionary games that they have been used productively not only in the social sciences but in biological and philosophical research as well.

The best way to understand the general idea of evolutionary games is by contrasting them with the rational choice methodology in game theory. In a rational choice model, one assumes that people are perfectly rational and self-interested, acting only to increase their own payoffs. These payoffs may be understood as financial rewards or any other positive outcomes.

Although rational choice models are powerful, and often appropriate, it is now known that humans often do not behave in a perfectly rational and self-interested manner. Instead, they often lack the cognitive sophistication
required to compute their optimal behavior, while at other times they are motivated by emotional or other “irrational” factors. In such cases, it often turns out that the correct explanation of a particular behavior is etiological—that is, the behavior is the result of short-sighted evolutionary processes or trial-and-error learning, rather than a deliberate rational calculation. Thus, in the context of discussing evolutionary games, the term “evolution” refers generally to any process by which a group of individuals change their behavior in a strategic context.

 Accordingly, evolutionary games typically dispense with the assumption that people are rational. Instead, the typical evolutionary game-theoretic model assumes that the agents being examined are myopic, cognitively simple, and not motivated by any self-interest at all. In the most common type of evolutionary game, the agents are simply “hard-wired” to behave in a particular way. The model generates predictions by imposing a dynamic in which the most successful strategies are reproduced according to how successful they are.

 The evolutionary game that is undoubtedly the most well known is Robert Axelrod’s famous Prisoner’s Dilemma tournament, in which people were invited to submit strategies for playing the Iterated Prisoner’s Dilemma (1984). This is a game of tremendous importance in the social sciences because it is the simplest non-trivial model of situations in which there is a conflict between self-interested behavior and cooperation with another person. At the conclusion of the tournament, Axelrod considered what would happen in a population containing many copies of the submitted strategies if he introduced a dynamic in which the individuals in the population reproduced, with the most successful individuals having the most offspring, and where each offspring displayed the same behavior as their parent. There is now a large body of formal literature that has extended this idea, of which the best known is the “replicator dynamics” of Peter Taylor and Leo Jonker (1978).
